Chapter 1

Welcome to NIMBLE

NIMBLE is a system for building and sharing analysis methods for statistical models, especially for hierarchical models and computationally-intensive methods. This is an early version, 0.4. You can do quite a bit with it, but it has some rough edges and gaps, and we plan to keep expanding it. If you want to analyze data, we hope you will find something already useful. If you want to build algorithms, we hope you will program in NIMBLE and make an R package providing your method. We also hope you will join the mailing lists (R-nimble.org) and help improve NIMBLE by telling us what you want to do with it, what you like, and what could be better. We have a lot of ideas for how to improve it, but we want your help and ideas too.

1.1 Why something new?

There is a lot of statistical software out there. Why did we build something new? More and more, statistical models are being customized to the details of each project. That means it is often difficult to find a package whose set of available models and methods includes what you need. And more and more, statistical models are hierarchical, meaning they have some unobserved random variables between the parameters and the data. These may be random effects, shared frailties, latent states, or other such things. Or a model may be hierarchical simply due to putting Bayesian priors on parameters. Except for simple cases, hierarchical statistical models are often analyzed with computationally-intensive algorithms, the best known of which is Markov chain Monte Carlo (MCMC).

Several existing software systems have become widely used by providing a flexible way to say what the model is and then automatically providing an algorithm such as MCMC. When these work, and when MCMC is what you want, that's great. Unfortunately, there are a lot of hard models out there for which default MCMCs don't work very well. And there are also a lot of useful new and old algorithms that are not MCMC, but they can be hard to find implemented for the model you need, and you may have to go learn a new system to use a new algorithm. That's why we wanted to create a system that combines a flexible system for model specification – the BUGS language – with the ability to program with those models. That's the goal of NIMBLE.

1.2 What does NIMBLE do?

NIMBLE stands for Numerical Inference for statistical Models for Bayesian and Likelihood Estimation. Although NIMBLE was motivated by algorithms for hierarchical statistical models, you could use it for simpler models too.

You can think of NIMBLE as comprising three pieces:

1. A system for writing statistical models flexibly, which is an extension of the BUGS language¹.
2. A library of algorithms such as MCMC.
3. A language, called NIMBLE, embedded within and similar in style to R, for writing algorithms that operate on BUGS models.

Both BUGS models and NIMBLE algorithms are automatically processed into C++ code, compiled, and loaded back into R with seamless interfaces.

Since NIMBLE can compile R-like functions into C++ that use the Eigen library for fast linear algebra, it can be useful for making fast numerical functions with or without BUGS models involved².

One of the beauties of R is that many of the high-level analysis functions are themselves written in R, so it is easy to see their code and modify them. The same is true for NIMBLE: the algorithms are themselves written in the NIMBLE language.

1.3 How to use this manual

We emphasize that you can use NIMBLE for data analysis with the algorithms provided by NIMBLE without ever using the NIMBLE language to write algorithms. So as you get started, feel free to focus on Chapters 2-8. The algorithm library in Version 0.4 is just a start, so we hope you'll let us know what you want to see and consider writing it in NIMBLE. More about NIMBLE programming comes in Chapter 9.

¹But see Section 5.1 for information about both limitations and extensions to how NIMBLE handles BUGS right now.

²The packages `Rcpp` and `RcppEigen` provide different ways of connecting C++, the Eigen library and R. In those packages you program directly in C++, while in NIMBLE you program in an R-like fashion and the NIMBLE compiler turns it into C++. Programming directly in C++ allows full access to C++, while programming in NIMBLE allows simpler code.

Chapter 2

Lightning introduction

2.1 A brief example

Here we'll give a simple example of building a model and running some algorithms on the model, as well as creating our own user-specified algorithm. The goal is to give you a sense for what one can do in the system. Later sections will provide more detail.

We'll use the *pump* model example from BUGS¹. We could load the model from the standard BUGS example file formats (Section 5.3.2), but instead we'll show how to enter it directly in R.

In this “lightning introduction” we will:

1. Create the model for the pump example.
2. Compile the model.
3. Create a basic MCMC specification for the pump model.
4. Compile and run the MCMC
5. Customize the MCMC specification and compile and run that.
6. Create, compile and run a Monte Carlo Expectation Maximization (MCEM) algorithm, which illustrates some of the flexibility NIMBLE provides to combine R and NIMBLE.
7. Write a short `nimbleFunction` to generate simulations from designated nodes of any model.

2.2 Creating a model

First we define the model code, its constants, data, and initial values for MCMC.

```
pumpCode <- nimbleCode({
  for (i in 1:N){
    theta[i] ~ dgamma(alpha,beta)
    lambda[i] <- theta[i]*t[i]
    x[i] ~ dpois(lambda[i])
  }
})
```

¹The data set describes failure times of some pumps.

```

    }
    alpha ~ dexp(1.0)
    beta ~ dgamma(0.1,1.0)
  })

pumpConsts <- list(N = 10,
                  t = c(94.3, 15.7, 62.9, 126, 5.24,
                      31.4, 1.05, 1.05, 2.1, 10.5))

pumpData <- list(x = c(5, 1, 5, 14, 3, 19, 1, 1, 4, 22))

pumpInits <- list(alpha = 1, beta = 1,
                  theta = rep(0.1, pumpConsts$N))

```

Now let's create the model and look at some of its nodes.

```

pump <- nimbleModel(code = pumpCode, name = 'pump', constants = pumpConsts,
                  data = pumpData, inits = pumpInits)

## defining model...
## building model...
## setting data and initial values...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)
## model building finished

pump$getNodeNames()

## [1] "alpha"          "beta"
## [3] "lifted_d1_over_beta" "theta[1]"

## [9] 0.210 1.050

```

Notice that in the list of nodes, NIMBLE has introduced a new node, `lifted_d1_over_beta`. We call this a “lifted” node. Like R, NIMBLE allows alternative parameterizations, such as the scale or rate parameterization of the gamma distribution. Choice of parameterization can generate a lifted node, as can using a link function or a distribution argument that is an expression. It’s helpful to know why they exist, but you shouldn’t need to worry about them.

Thanks to the plotting capabilities of the `igraph` package that NIMBLE uses to represent the directed acyclic graph, we can plot the model (figure 2.1).

```
plot(pump$graph)
```

You are in control of the model. By default, `nimbleModel` does its best to initialize a model, but let’s say you want to re-initialize `theta`. To simulate from the prior for `theta` (overwriting the initial values previously in the model) we first need to be sure the parent nodes of all `theta[i]` nodes are fully initialized, including any non-stochastic nodes such as lifted nodes. We then use the `simulate` function to simulate from the distribution for `theta`. Finally we use the `calculate` function to calculate the dependencies of `theta`, namely `lambda` and the log probabilities of `x` to ensure all parts of the model are up to date. First we show how to use the model’s `getDependencies` method to query information about its graph.

```
## Show all dependencies of alpha and beta terminating in stochastic nodes
pump$getDependencies(c('alpha', 'beta'))
```

Figure 2.1: Directed Acyclic Graph plot of the pump model, thanks to the igraph package

```

## [1] "alpha" "beta"
## [3] "lifted_d1_over_beta" "theta[1]"
## [5] "theta[2]" "theta[3]"
## [7] "theta[4]" "theta[5]"
## [9] "theta[6]" "theta[7]"
## [11] "theta[8]" "theta[9]"
## [13] "theta[10]"

## Now show only the deterministic dependencies
pump$getDependencies(c('alpha', 'beta'), determOnly = TRUE)

## [1] "lifted_d1_over_beta"

## Check that the lifted node was initialized.
pump[["lifted_d1_over_beta"]] ## It was.

## [1] 1

## Now let's simulate new theta values
set.seed(0) ## This makes the simulations here reproducible
simulate(pump, 'theta')
pump$theta ## the new theta values

## [1] 1.79180692 0.29592523 0.08369014 0.83617765 1.22254365
## [6] 1.15835525 0.99001994 0.30737332 0.09461909 0.15720154

## lambda and logProb_x haven't been re-calculated yet
pump$lambda ## these are the same values as above

## [1] 9.430 1.570 6.290 12.600 0.524 3.140 0.105 0.105
## [9] 0.210 1.050

pump$logProb_x

## [1] -2.998011 -1.118924 -1.882686 -2.319466 -4.254550
## [6] -20.739651 -2.358795 -2.358795 -9.630645 -48.447798

getLogProb(pump, 'x') ## The sum of logProb_x

## [1] -96.10932

calculate(pump, pump$getDependencies(c('theta')))

## [1] -286.6951

pump$lambda ## Now they have.

## [1] 168.9673926 4.6460261 5.2641096 105.3583839 6.4061287
## [6] 36.3723548 1.0395209 0.3227420 0.1987001 1.6506161

pump$logProb_x

## [1] -148.106356 -3.110014 -1.747041 -65.346457 -2.626123
## [6] -7.429868 -1.000761 -1.453644 -9.840589 -39.096527

```

Notice that the first `getDependencies` call returned dependencies from `alpha` and `beta` down to the next stochastic nodes in the model. The second call requested only deterministic dependencies. The call to `calculate(pump, 'theta')` expands `'theta'` to include all nodes in `theta`. After simulating into `theta`, we can see that `lambda` and the log probabilities of `x` still reflect the old values of `theta`, so we `calculate` them and then see that they have been updated.

2.3 Compiling the model

Next we compile the model, which means generating C++ code, compiling that code, and loading it back into R with an object that can be used just like the uncompiled model. The values in the compiled model will be initialized from those of the original model in R, but the original and compiled models are distinct objects so any subsequent changes in one will not be reflected in the other.

```
Cpump <- compileNimble(pump)
Cpump$theta

## [1] 1.79180692 0.29592523 0.08369014 0.83617765 1.22254365
## [6] 1.15835525 0.99001994 0.30737332 0.09461909 0.15720154
```

Note that the compiled model is used when running any NIMBLE algorithms via C++, so the model needs to be compiled before (or at the same time as) any compilation of algorithms, such as the compilation of the MCMC done in the next section.

2.4 Creating, compiling and running a basic MCMC specification

At this point we have initial values for all of the nodes in the model and we have both the original and compiled versions of the model. As a first algorithm to try on our model, let's use NIMBLE's default MCMC. Note that conjugate relationships are detected for all nodes except for `alpha`, on which the default sampler is a random walk Metropolis sampler.

```
pumpSpec <- configureMCMC(pump, print = TRUE)

## [1] RW sampler: alpha, adaptive: TRUE, adaptInterval: 200, scale: 1
## [2] conjugate_dgamma sampler: beta, dependents_dgamma: theta[1], theta[2], theta[3],
## [3] conjugate_dgamma sampler: theta[1], dependents_dpois: x[1]
## [4] conjugate_dgamma sampler: theta[2], dependents_dpois: x[2]
## [5] conjugate_dgamma sampler: theta[3], dependents_dpois: x[3]
## [6] conjugate_dgamma sampler: theta[4], dependents_dpois: x[4]
## [7] conjugate_dgamma sampler: theta[5], dependents_dpois: x[5]
## [8] conjugate_dgamma sampler: theta[6], dependents_dpois: x[6]
```

```
## [9] conjugate_dgamma sampler: theta[7], dependents_dpois: x[7]
## [10] conjugate_dgamma sampler: theta[8], dependents_dpois: x[8]
## [11] conjugate_dgamma sampler: theta[9], dependents_dpois: x[9]
## [12] conjugate_dgamma sampler: theta[10], dependents_dpois: x[10]

pumpSpec$addMonitors(c('alpha', 'beta', 'theta'))

## thin = 1: alpha, beta, theta

pumpMCMC <- buildMCMC(pumpSpec)
CpumpMCMC <- compileNimble(pumpMCMC, project = pump)

niter <- 1000
set.seed(0)
CpumpMCMC$run(niter)

## NULL

samples <- as.matrix(CpumpMCMC$mvSamples)

par(mfrow = c(1, 4), mai = c(.6, .5, .1, .2))
plot(samples[, 'alpha'], type = 'l', xlab = 'iteration',
      ylab = expression(alpha))
plot(samples[, 'beta'], type = 'l', xlab = 'iteration',
      ylab = expression(beta))
plot(samples[, 'alpha'], samples[, 'beta'], xlab = expression(alpha),
      ylab = expression(beta))
plot(samples[, 'theta[1]'], type = 'l', xlab = 'iteration',
      ylab = expression(theta[1]))
```

```
acf(samples[, 'alpha']) ## plot autocorrelation of alpha sample
acf(samples[, 'beta']) ## plot autocorrelation of beta sample
```

Notice the posterior correlation between `alpha` and `beta`. A measure of the mixing for each is the autocorrelation for each parameter, shown by the `acf` plots.

2.5 Customizing the MCMC

Let's add an adaptive block sampler on `alpha` and `beta` jointly and see if that improves the mixing.

```
pumpSpec$addSampler(target = c('alpha', 'beta'), type = 'RW_block',
                    control = list(adaptInterval = 100))
## [13] RW_block sampler: alpha, beta, adaptive: TRUE, adaptScaleOnly: FALSE, adaptIn
pumpMCMC2 <- buildMCMC(pumpSpec)

# need to reset the nimbleFunctions in order to add the new MCMC
CpumpNewMCMC <- compileNimble(pumpMCMC2, project = pump,
                              resetFunctions = TRUE)

set.seed(0);
CpumpNewMCMC$run(niter)
## NULL

samplesNew <- as.matrix(CpumpNewMCMC$mvSamples)

par(mfrow = c(1, 4), mai = c(.6, .5, .1, .2))
plot(samplesNew[, 'alpha'], type = 'l', xlab = 'iteration',
      ylab = expression(alpha))
plot(samplesNew[, 'beta'], type = 'l', xlab = 'iteration',
      ylab = expression(beta))
plot(samplesNew[, 'alpha'], samplesNew[, 'beta'], xlab = expression(alpha),
      ylab = expression(beta))
plot(samplesNew[, 'theta[1]'], type = 'l', xlab = 'iteration',
      ylab = expression(theta[1]))
```

```
acf(samplesNew[, 'alpha']) ## plot autocorrelation of alpha sample
acf(samplesNew[, 'beta'])  ## plot autocorrelation of beta sample
```

We can see that the block sampler has decreased the autocorrelation for both **alpha** and **beta**. Of course these are just short runs, and what we are really interested in is the effective sample size of the MCMC per computation time, but that's not the point of this example.

Once you learn the MCMC system, you can write your own samplers and include them. The entire system is written in `nimbleFunctions`.

2.6 Running MCEM

NIMBLE is a system for working with algorithms, not just an MCMC engine. So let's try maximizing the marginal likelihood for **alpha** and **beta** using Monte Carlo Expectation Maximization².

```
pump2 <- pump$newModel()
```

²Note that for this model, one could analytically integrate over **theta** and then numerically maximize the resulting marginal likelihood.

```

## setting data and initial values...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)

box = list( list(c('alpha','beta'), c(0, Inf)))

pumpMCEM <- buildMCEM(model = pump2, latentNodes = 'theta[1:10]',
                      boxConstraints = box)

pumpMLE <- pumpMCEM()
# Note: buildMCEM returns an R function that contains a
# nimbleFunction rather than a nimble function. That is why
# pumpMCEM() is used instead of pumpMCEM\lrun().

pumpMLE

##      alpha      beta
## 0.8230659 1.2600147

```

Both estimates are within 0.01 of the values reported by George et al. [2]³. Some discrepancy is to be expected since it is a Monte Carlo algorithm.

2.7 Creating your own functions

Now let's see an example of writing our own algorithm and using it on the model. We'll do something simple: simulating multiple values for a designated set of nodes and calculating every part of the model that depends on them.

Here is our `nimbleFunction`:

```

simNodesMany <- nimbleFunction(
  setup = function(model, nodes) {
    mv <- modelValues(model)
    deps <- model$getDependencies(nodes)
    allNodes <- model$getNodeNames()
  },
  run = function(n = integer()) {
    resize(mv, n)
    for(i in 1:n) {
      simulate(model, nodes)
      calculate(model, deps)
      copy(from = model, nodes = allNodes,
           to = mv, rowTo = i, logProb = TRUE)
    }
  })

```

³Their numbers were accidentally swapped in Table 2.

```
simNodesTheta1to5 <- simNodesMany(pump, 'theta[1:5]')
simNodesTheta6to10 <- simNodesMany(pump, 'theta[6:10]')
```

Here are a few things to notice about the `nimbleFunction`

1. The `setup` function is written in R. It creates relevant information specific to our model for use in the run-time code.
2. The `setup` code creates a `modelValues` object to hold multiple sets of values for variables in the model provided.
3. The `run` function is written in NIMBLE. It carries out the calculations using the information determined once for each set of `model` and `nodes` arguments by the setup code. The run-time code is what will be compiled.
4. The `run` code requires type information about the argument `n`. In this case it is a scalar integer.
5. The for-loop looks just like R, but only sequential integer iteration is allowed.
6. The functions `calculate` and `simulate`, which were introduced above in R, can be used in NIMBLE.
7. The special function `copy` is used here to record values from the model into the `modelValues` object.
8. Multiple instances, or “specializations”, can be made by calling `simNodesMany` with different arguments. Above, `simNodesTheta1to5` has been made by calling `simNodesMany` with the `pump` model and nodes `'theta[1:5]'` as inputs to the `setup` function, while `simNodesTheta6to10` differs by providing `'theta[6:10]'` as an argument. The returned objects are objects of a uniquely generated R reference class with fields (member data) for the results of the `setup` code and a `run` method (member function). Arbitrary other methods can be provided with a `methods` argument, following the syntax of R’s `setRefClass` function.

By the way, `simNodesMany` is very similar to a standard `nimbleFunction` provided with `nimble`, `simNodesMV`.

Now let’s execute this `nimbleFunction` in R, before compiling it.

```
set.seed(0) ## make the calculation repeatable
pump$alpha <- pumpMLE[1]
pump$beta <- pumpMLE[2]
## make sure to update deterministic dependencies of the altered nodes
calculate(pump, pump$getDependencies(c('alpha','beta'), determOnly = TRUE))

## [1] 0

saveTheta <- pump$theta
simNodesTheta1to5$run(10)
simNodesTheta1to5$mv[['theta']][1:2]
```

```
## [[1]]
## [1] 1.43717729 1.53093576 1.45028779 0.03716752 0.13310071

## [6] -7.429868 -1.000761 -1.453644 -9.840589 -39.096527
```

In this code we have initialized the values of `alpha` and `beta` to their MLE and then recorded the `theta` values to use below. Then we have requested 10 simulations from `simNodesTheta1to5`. Shown are the first two simulation results for `theta` and the log probabilities of `x`. Notice that `theta[6:10]` and the corresponding log probabilities for `x[6:10]` are unchanged because the nodes being simulated are only `theta[1:5]`. In R, this function runs slowly.

Finally, let's compile the function and run that version.

```
CsimNodesTheta1to5 <- compileNimble(simNodesTheta1to5,
                                   project = pump, resetFunctions = TRUE)
Cpump$alpha <- pumpMLE[1]
Cpump$beta <- pumpMLE[2]
calculate(Cpump, Cpump$getDependencies(c('alpha', 'beta'), determOnly = TRUE))

## [1] 0

Cpump$theta <- saveTheta

set.seed(0)
CsimNodesTheta1to5$run(10)

## NULL

CsimNodesTheta1to5$mv[['theta']][1:2]

## [[1]]
## [1] 1.43717729 1.53093576 1.45028779 0.03716752 0.13310071
```

```
## [6] 1.15835525 0.99001994 0.30737332 0.09461909 0.15720154
##

CsimNodesTheta1to5$mv[['logProb_x']][1:2]

## [[1]]
## [1] -115.767500 -20.856152 -73.444053 -8.258863 -3.570190
## [6] -2.593423 -1.006239 -1.180023 -1.757379 -2.531520
##
## [[2]]
## [1] -19.688263 -50.299758 -37.107538 -2.598331 -1.825300
## [6] -2.593423 -1.006239 -1.180023 -1.757379 -2.531520
```

Given the same initial values and the same random number generator seed, we got identical results for `theta[1:5]` and their dependencies, but it happened much faster.

Chapter 3

More Introduction

Now that we have shown a brief example, we will introduce more about the concepts and design of NIMBLE. Subsequent chapters will go into more detail about working with models and programming in NIMBLE.

One of the most important concepts behind NIMBLE is to allow a combination of high-level processing in R and low-level processing in compiled C++. For example, when we write a Metropolis-Hastings MCMC sampler in the NIMBLE language, the inspection of the model structure related to one node is done in R, and the actual sampler calculations are done in compiled C++. The theme of separating one-time high-level processing and repeated low-level processing will become clearer as we introduce more about NIMBLE's components.

3.1 NIMBLE adopts and extends the BUGS language for specifying models

We adopted the BUGS language, and we have extended it to make it more flexible. The BUGS language became widely used in WinBUGS, then in OpenBUGS and JAGS. These systems all provide automatically-generated MCMC algorithms, but we have adopted only the language for describing models, not their systems for generating MCMCs. We adopted BUGS because it has been so successful, with over 30,000 users by the time they stopped counting [3]. Many papers and books provide BUGS code as a way to document their statistical models. We provide a brief introduction to BUGS later, but we refer you to the WinBUGS, OpenBUGS or JAGS websites for more material. For the most part, if you have BUGS code, you can try NIMBLE.

NIMBLE takes BUGS code and does several things with it:

1. NIMBLE extracts all the declarations in the BUGS code to create a *model definition*. This includes a directed acyclic graph (DAG) representing the model and functions that can query model relationships from the graph. Usually you'll ignore the *model definition* and let NIMBLE's default options take you directly to the next step.
2. From the *model definition*, NIMBLE builds a working model in R. This can be used to manipulate variables and operate the model from R. Operating the model includes

calculating, simulating, or querying the log probability value of model nodes. These basic capabilities, along with the tools to query model structure, allow one to write programs that use the model and adapt to its structure.

3. From the working model, NIMBLE generates customized C++ code representing the model, compiles the C++, loads it back into R, and provides an R object that interfaces to it. We often call the uncompiled model the “R-model” and the compiled model the “C-model.” The C-model can be used identically to the R-model, so code written to use one will work with the other. We use the word “compile” to refer to the entire process of generating C++ code, compiling it and loading it into R.

More about specifying and manipulating models is in Chapter 5-6.

3.2 The NIMBLE language for writing algorithms

NIMBLE provides a language, embedded within and similar in style to R, for writing algorithms that can operate on BUGS models. The algorithms can use NIMBLE’s utilities for inspecting the structure of a model, such as determining the dependencies between variables. And the algorithms can control the model, changing values of its variables and controlling execution of its probability calculations or corresponding simulations. Finally, the algorithms can use automatically generated data structures to manage sets of model values and probabilities. In fact, the calculations of the model are themselves constructed as functions in the NIMBLE language, as are the algorithms provided in NIMBLE’s algorithm library. This means that you can extend BUGS with new distributions and new functions written in NIMBLE.

Like the models themselves, functions in the NIMBLE language are turned into C++, which is compiled, loaded, and interfaced to R.

Programming in NIMBLE involves a fundamental distinction between:

1. the steps for an algorithm that need to happen only once, at the beginning, such as inspecting the model; and
2. the steps that need to happen each time a function is called, such as MCMC iterations.

When one writes a `nimbleFunction`, each of these parts can be provided separately. The former, if needed, are given in a *setup function*, and they are executed directly in R, allowing any feature of R to be used. The latter are in one or more *run-time functions*, and they are turned into C++. Run-time code is written in the NIMBLE language, which you can think of as a carefully controlled, small subset of R along with some special functions for handling models and NIMBLE’s data structures.

What NIMBLE does with a `nimbleFunction` is similar to what it does with a BUGS model:

1. NIMBLE creates a working R version of the `nimbleFunction`, which you can use with an R-model or a C-model.
2. NIMBLE generates C++ code for the run-time function(s), compiles it, and loads it back into R with an interface nearly identical to the R version of the `nimbleFunction`. As with models, we refer to the uncompiled and compiled versions as R-nimbleFunctions

and C-nimbleFunctions, respectively. In v0.4, the behavior of `nimbleFunctions` is usually very similar, but not identical, between the two versions. The primary purpose of uncompiled execution is to facilitate debugging.

More about writing algorithms is in Chapter 9.

3.3 The NIMBLE algorithm library

In v0.4, the NIMBLE algorithm library includes:

1. MCMC with samplers including conjugate, slice, adaptive random walk, and adaptive block random walk. NIMBLE's MCMC system illustrates the flexibility of combining R and C++. An R function inspects the model object and creates an MCMC specification object representing choices of which kind of sampler to use for each node. This MCMC specification can be modified in R, such as adding new samplers for particular nodes, before compiling the algorithm. Since each sampler is written in NIMBLE, you can use its source code or write new samplers to insert into the MCMC. And if you want to build an entire MCMC system differently, you can do that too.
2. A `nimbleFunction` that provides a likelihood function for arbitrary sets of nodes in any model. This can be useful for simple maximum likelihood estimation of non-hierarchical models using R's optimization functions. And it can be useful for other R packages that run algorithms on any likelihood function.
3. A `nimbleFunction` that provides ability to simulate, calculate, or retrieve the summed log probability (density) of many sets of values for arbitrary sets of nodes.
4. A `nimbleFunction` that provides a basic particle filter for a state-space model.
5. A basic Monte Carlo Expectation Maximization (MCEM) algorithm. MCEM has its issues as an algorithm, such as potentially slow convergence to the maximum likelihood (i.e., empirical Bayes in this context) estimates, but we chose it as a good illustration of how NIMBLE can be used. Each MCMC step uses NIMBLE's MCMC; the objective function for maximization is another `nimbleFunction`; and the actual maximization is done through R's `optim` function¹.

More about the NIMBLE algorithm library is in Chapter 8.

¹In the future we plan to provide direct access to R's optimizers from within `nimbleFunctions`.

Chapter 4

Installing NIMBLE

4.1 Requirements to run NIMBLE

You can run NIMBLE on any of the three common operating systems: Linux, Mac OS X, or Windows.

The following are required to run NIMBLE.

1. **R**, of course.
2. The **igraph** R package.
3. A working C++ compiler that R can use on your system. There are standard open-source C++ compilers that the R community has already made easy to install. You don't need to know anything about C++ to use NIMBLE.

NIMBLE also uses a couple of C++ libraries that you don't need to install, as they will already be on your system or are provided by NIMBLE.

1. The **Eigen** C++ library for linear algebra. This comes with NIMBLE, or you can use your own copy.
2. The BLAS and LAPACK numerical libraries. These come with R.

Most fairly recent versions of these requirements should work.

4.2 Installation

Since NIMBLE is an R package, you can install it in the usual way, via `install.packages` or related mechanisms. We have not yet put it in on CRAN, so you'll have to find it at R-nimble.org.

For most installations, you can ignore low-level details. However, there are some options that some users may want to utilize.

4.2.1 Using your own copy of Eigen

NIMBLE uses the Eigen C++ template library for linear algebra. Version 3.2.1 of Eigen is included in the NIMBLE package and that version will be used unless the package's

configuration script finds another version on the machine. This works well, and the following is only relevant if you want to use a different (e.g., newer) version.

The configuration script looks in the standard include directories, e.g. `/usr/include` and `/usr/local/include` for the header file `Eigen/Dense`. You can specify a particular location in either of two ways:

1. Set the environment variable `EIGEN_DIR` before installing the R package, e.g., `export EIGEN_DIR=/usr/include/eigen3` in the bash shell.
2. Use R CMD `INSTALL --configure-args='--with-eigen=/path/to/eigen'` `nimble_VERSION.tar.`
or
`install.packages("nimble", configure.args = "--with-eigen=/path/to/eigen").`

In these cases, the directory should be the full path to the directory that contains the Eigen directory, e.g. `/usr/include/eigen3`. It is not the full path to the Eigen directory itself, i.e., NOT `/usr/include/eigen3/Eigen`.

4.2.2 Using libnimble

NIMBLE generates specialized C++ code for user-specified models and `nimbleFunctions`. This code uses some NIMBLE C++ library classes and functions. By default, on Linux and OS X, the library code is compiled once as a linkable library - *libnimble*. This single instance of the library is then linked with the code for each generated model. Alternatively, one can have the library code recompiled in each model's own dynamically loadable library (DLL). This does repeat the same code across models and so occupies more memory. There may be a marginal speed advantage. This is currently what happens on Windows. One can disable using *libnimble* via the configuration argument `--enable-lib`, e.g.,

```
R CMD INSTALL --configure-args='--enable-lib=false' nimble_VERSION.tar.gz
```

4.2.3 LAPACK and BLAS

NIMBLE also uses BLAS and LAPACK for some of its linear algebra (in particular calculating density values and generating random samples from multivariate distributions). NIMBLE will use the same BLAS and LAPACK installed on your system that R uses. Note that a fast (and where appropriate, threaded) BLAS can greatly increase the speed of linear algebra calculations. See Section A.3.1 of the R Installation and Administration manual for more details on providing a fast BLAS for your R installation.

4.2.4 Problems with Installation

We have tested the installation on the three commonly used platforms – OS X, Linux, Windows¹. We don't anticipate problems with installation, but we want to hear about any and help resolve them. Please post about installation problems to the `nimble-users` Google group or email `nimble.stats@gmail.com`.

¹We've tested NIMBLE on Windows 7 and 8

4.3 Installing a C++ compiler for R to use

In addition to needing a C++ compiler to install the package (from source), you also need to have a C++ compiler and the utility *make* at run-time. This is needed during the R session to compile the C++ code that NIMBLE generates for a user's models and algorithms.

4.3.1 OS X

On OS X, you should install *Xcode*. The command-line tools, which are available as a smaller installation, should be sufficient. This is freely available from the [Apple developer site](#) and the [App Store](#).

For the compiler to work correctly for OS X, it is very important that the installed R be matched to the correct OS, i.e. R for Snow Leopard will attempt to use the incorrect compiler if the user has OS 10.9 or higher.

4.3.2 Linux

On Linux, you can install the GNU compiler suite (*gcc/g++*). You can use the package manager to install pre-built binaries. On Ubuntu, the following command will install or update *make*, *gcc* and *libc*.

```
sudo apt-get install build-essential
```

4.3.3 Windows

On Windows, you should download and install *Rtools.exe* available from <http://cran.r-project.org/bin/windows/Rtools/>. Select the appropriate executable corresponding to your version of R. (We strongly recommend using the most recent version of R, currently 3.2.1, and hence *Rtools33.exe*). This installer leads you through several “pages”. We think you can accept the defaults with one exception: check the PATH checkbox (page 5) so that the installer will add the location of the C++ compiler and related tools to your system's PATH, ensuring that R can find them. After you click “Next”, you will get a page with a window for customizing the new PATH variable. You shouldn't need to do anything there, so you can simply click “Next” again.

We note that it is essential the checkbox for the “R 2.15+ toolchain” (page 4) be enabled in order to have *gcc/g++*, *make*, etc. installed. This should be checked by default.

Advanced users may wish to change their default compilers. This can be done by editing the *Makevars* file, see Writing R Externsions: 1.2.1.

4.4 Customizing Compilation of the NIMBLE-generated Code

For each model or *nimbleFunction*, the NIMBLE package generates and compiles C++ code. This uses classes and routines available through the NIMBLE run-time library and also

the Eigen library. The compilation mechanism uses R's SHLIB functionality and therefore uses the regular R configuration in $\${R_HOME}/etc\${R_ARCH}/Makeconf$. NIMBLE places a *Makevars* file in the directory in which the code is generated and R CMD SHLIB uses this file.

In all but specialized cases, the general compilation mechanism will suffice. However, one can customize this. One can specify the location of an alternative *Makevars* (or *Makevars.win*) file to use. Such an alternative file should define the variables `PKG_CPPFLAGS` and `PKG_LIBS`. These should contain, respectively, the pre-processor flag to locate the NIMBLE include directory, and the necessary libraries to link against (and their location as necessary), e.g., *Rlapack* and *Rblas* on Windows, and *libnimble*.

Use of this file allows users to specify additional compilation and linking flags. See the Writing R Extensions manual for more details of how this can be used and what it can contain.

Chapter 5

Building models

NIMBLE aims to be compatible with the original BUGS language and also the version used by the popular JAGS package, as well as to extend the BUGS language. However, at this point, there are some BUGS features not supported by NIMBLE, and there are some extensions that are planned but not implemented.

For readers familiar with BUGS, we begin with an overview of supported features and extensions.

5.1 Overview of supported features and extensions of BUGS and JAGS

5.1.1 Supported features of BUGS and JAGS

1. Stochastic and deterministic¹ node declarations.
2. Most univariate and multivariate distributions.
3. Link functions.
4. Most mathematical functions.
5. “for” loops for iterative declarations.
6. Arrays of nodes up to 4 dimensions.
7. Truncation and censoring as in JAGS using the `T()` notation and `dinterval`.

5.1.2 NIMBLE’s Extensions to BUGS and JAGS

NIMBLE extends the BUGS language in the following ways:

1. User-defined functions and distributions – written as `nimbleFunctions` – can be used in model code. See Section 5.2.5.
2. Multiple parameterizations for distributions, similar to those in R, can be used.
3. Named parameters for distributions and functions, similar to R function calls, can be used.

¹NIMBLE calls non-stochastic nodes “deterministic”, whereas BUGS calls them “logical”. NIMBLE uses “logical” in the way R does, to refer to boolean (TRUE/FALSE) variables.

4. Distribution parameters can be expressions², as in JAGS but not in WinBUGS. Caveat: parameters to *multivariate* distributions (e.g., `dmnorm`) cannot be expressions.
5. Alternative models can be defined from the same model code by using if-then-else statements that are evaluated when the model is defined.
6. More flexible indexing of vector nodes within larger variables is allowed. For example one can place a multivariate normal vector arbitrarily within a higher-dimensional object, not just in the last index.
7. More general constraints can be declared using `dconstraint`, which extends the concept of JAGS' `dinterval`. See Section 5.2.8.
8. Link functions can be used in stochastic, as well as deterministic, declarations.³
9. Data values can be reset, and which parts of a model are flagged as data can be changed, allowing one model to be used for different data sets without rebuilding the model each time.

5.1.3 Not-yet-supported features of BUGS and JAGS

In this release, the following are not supported.

1. Stochastic indices (but see Section 5.2.5 for a description of how you could handle some cases with user-defined distributions).
2. The appearance of the same node on the left-hand side of both a `<-` and a `~` declaration (used in WinBUGS for data assignment for the value of a stochastic node).
3. Like BUGS, NIMBLE generally determines the dimensionality and sizes of variables from the BUGS code. However, when a variable appears with blank indices, such as in `x.sum <- sum(x[])`, NIMBLE currently requires that the dimensions of `x` be provided.
4. Multivariate nodes must appear with brackets, even if they are empty. E.g., `x` cannot be multivariate but `x[]` or `x[2:5]` can be.

5.2 Writing models

5.2.1 Declaring stochastic and deterministic nodes

The WinBUGS, OpenBUGS and JAGS manuals are useful resources for writing BUGS models. Here we will just introduce the basics of the BUGS language – and some of NIMBLE's extensions – with a block of code showing a variety of declarations:

```
exampleCode <- nimbleCode({
  ## 1. normal distribution with BUGS parameter order
  x ~ dnorm(a + b * c, tau)
  ## 2. normal distribution with a named parameter
  y ~ dnorm(a + b * c, sd = sigma)
```

²e.g., `y ~ dnorm(5 + mu, 3 * exp(tau))`

³But beware of the possibility of needing to set values for “lifted” nodes created by NIMBLE.

```

## 3. For-loop and nested indexing
for(i in 1:N) {
  for(j in 1:M[i]) {
    z[i,j] ~ dexp(r[ blockID[i] ])
  }
}
## 4. multivariate distribution with arbitrary indexing
for(i in 1:3)
  mvx[8:10, i] ~ dmnorm(mvMean[3:5], cov = mvCov[1:3, 1:3, i])
## 5. User-provided distribution
w ~ dMyDistribution(hello = x, world = y)
## 6. Simple deterministic node
d1 <- a + b
## 7. Vector deterministic node with matrix multiplication
d2[] <- A[ , ] %*% mvMean[1:5]
## 8. Deterministic node with user-provided function
d3 <- foo(x, hooray = y)
})

```

This code does not show a complete model and includes some arbitrary indices (e.g. `mvx[8:10, i]`) to illustrate flexibility. When a variable appears only on the right-hand side, it must be provided in data or constants. Notes on the comment-numbered lines are:

1. `x` follows a normal distribution with mean `a + b*c` and precision `tau` (default BUGS second parameter for `dnorm`).
2. `y` follows a normal distribution with the same mean as `x` but a named standard deviation parameter instead of a precision parameter (`sd = 1/sqrt(precision)`).
3. `z[i, j]` follows an exponential distribution with parameter `r[blockID[i]]`. This shows how for-loops can be used for indexing of variables containing multiple nodes. Nested indexing can be used if the nested indices (`blockID`) are provided as constants when the model is defined (via `nimbleModel` or `readBUGSmodel`). Variables that define for-loop indices (`N` and `M`) must be provided as constants.
4. The arbitrary block `mvx[8:10, i]` follows a multivariate normal distribution, with a named covariance matrix instead of BUGS' default of a precision matrix. As in R, curly braces for for-loop contents are only needed if there is more than one line.
5. `w` follows a user-defined distribution. See Section 5.2.5.
6. `d1` is a scalar deterministic node that, when calculated, will be set to `a + b`.
7. `d2` is a vector deterministic node using matrix multiplication in R's syntax.
8. `d3` is a deterministic node using a user-provided function. See Section 5.2.5.

More about indexing

Examples of allowed indexing include:

- `x[i]`

- `x[i:j]`
- `x[i:j,k:1]` and indexing of higher dimensional arrays
- `x[i:j,]`
- `x[3*i+7]`
- `x[(3*i):(5*i+1)]`

When calling functions such as `mean` and `sum` on a vector variable, the square brackets are required but can have blank indices, e.g. `xbar <- mean(x[])` if `x` is a vector and `xbar <- mean(x[,])` if `x` is a matrix⁴.

NIMBLE does not allow multivariate nodes to be indicated without square brackets, which is an incompatibility with JAGS. Therefore a statement like `xbar <- mean(x)` in JAGS must be converted to `xbar <- mean(x[])` for NIMBLE.

Here's an example of indexing in the context of multivariate nodes, showing two ways to do the indexing. The first provides indices, so no `dimensions` argument is needed, while the second omits the indices and provides a `dimensions` argument instead.

```
code <- nimbleCode({
  y[1:K] ~ dmulti(p[1:K], n)
  p[1:K] ~ ddirch(alpha[1:K])
  log(alpha[1:K]) ~ dnorm(alpha0[1:K], R[1:K, 1:K])
})

K <- 5
model <- nimbleModel(code, constants = list(n = 3, K = K,
                                           alpha0 = rep(0, K), R = diag(K)),
                    check = FALSE)

## defining model...
## building model...
## model building finished

codeAlt <- nimbleCode({
  y[] ~ dmulti(p[], n)
  p[] ~ ddirch(alpha[])
  log(alpha[]) ~ dnorm(alpha0[], R[ , ])
})

model <- nimbleModel(codeAlt, constants = list(n = 3, K = K,
                                              alpha0 = rep(0, K), R = diag(K)),
                    dimensions = list(y = K, p = K, alpha = K),
                    check = FALSE)

## defining model...
## building model...
## model building finished
```

⁴This is a case where the dimension of `x` must be provided when defining the model.

5.2.2 Available distributions and functions

Distributions

NIMBLE supports most of the distributions allowed in BUGS and JAGS. Table 5.1 lists the distributions that are currently supported, with their default parameterizations, which match those of BUGS. NIMBLE also allows one to use alternative parameterizations for a variety of distributions as described next.

Note that the same distributions are available for writing `nimbleFunctions`, but in that case the default parameterizations match R's when possible (see Chapter 9).

Table 5.1: Distributions with their default order of parameters. The value of the random variable is denoted by x .

Name	Usage	Density	Lower	Upper
Bernoulli	<code>dbern(prob = p)</code> $0 < p < 1$	$p^x(1-p)^{1-x}$	0	1
Beta	<code>dbeta(shape1 = a, shape2 = b)</code> $a > 0, b > 0$	$\frac{x^{a-1}(1-x)^{b-1}}{\beta(a, b)}$	0	1
Binomial	<code>dbin(prob = p, size = n)</code> $0 < p < 1, n \in \mathbb{N}^*$	$\binom{n}{x} p^x (1-p)^{n-x}$	0	n
Categorical	<code>dcat(prob = p)</code> $p \in (\mathbb{R}^+)^N$	$\frac{p_x}{\sum_i p_i}$	1	N
Chi-square	<code>dchisq(df = k)</code> $k > 0$	$\frac{x^{\frac{k}{2}-1} \exp(-x/2)}{2^{\frac{k}{2}} \Gamma(\frac{k}{2})}$	0	
Dirichlet	<code>ddirch(alpha = α)</code> $\alpha_j \geq 0$	$\frac{x_j^{\alpha_j-1}}{\Gamma(\sum_i \alpha_i) \prod_j \Gamma(\alpha_j)}$	0	
Exponential	<code>dexp(rate = λ)</code> $\lambda > 0$	$\lambda \exp(-\lambda x)$	0	
Gamma	<code>dgamma(shape = r, rate = λ)</code> $\lambda > 0, r > 0$	$\frac{\lambda^r x^{r-1} \exp(-\lambda x)}{\Gamma(r)}$	0	
Logistic	<code>dlogis(location = μ, rate = τ)</code> $\tau > 0$	$\frac{\tau \exp\{(x-\mu)\tau\}}{[1 + \exp\{(x-\mu)\tau\}]^2}$		
Log-normal	<code>dlnorm(meanlog = μ, tau = τ)</code> $\tau > 0$	$(\frac{\tau}{2\pi})^{\frac{1}{2}} x^{-1} \exp\{-\tau(\log(x) - \mu)^2/2\}$	0	
Multinomial	<code>dmulti(prob = p, size = n)</code> $\sum_j x_j = n$	$n! \prod_j \frac{p_j^{x_j}}{x_j!}$		
Multivariate normal	<code>dnorm(mean = μ, prec = Λ)</code> Λ positive definite	$(2\pi)^{-\frac{d}{2}} \Lambda ^{\frac{1}{2}} \exp\{-(x-\mu)^T \Lambda (x-\mu)/2\}$		
Negative binomial	<code>dnegbin(prob = p, size = r)</code> $0 < p \leq 1, r \geq 0$	$\binom{x+r-1}{x} p^r (1-p)^x$	0	
Normal	<code>dnorm(mean = μ, tau = τ)</code> $\tau > 0$	$(\frac{\tau}{2\pi})^{\frac{1}{2}} \exp\{-\tau(x-\mu)^2/2\}$		
Poisson	<code>dpois(lambda = λ)</code> $\lambda > 0$	$\frac{\exp(-\lambda) \lambda^x}{x!}$	0	
Student t	<code>dt(mu = μ, tau = τ, df = k)</code> $\tau > 0, k > 0$	$\frac{\Gamma(\frac{k+1}{2})}{\Gamma(\frac{k}{2})} (\frac{\tau}{k\pi})^{\frac{1}{2}} \left\{1 + \frac{\tau(x-\mu)^2}{k}\right\}^{-\frac{(k+1)}{2}}$		

Table 5.1: Distributions with their default order of parameters. The value of the random variable is denoted by x .

Name	Usage	Density	Lower	Upper
Uniform	<code>dunif(min = a, max = b)</code> $a < b$	$\frac{1}{b-a}$	a	b
Weibull	<code>dweib(shape = v, lambda = λ)</code> $v > 0, \lambda > 0$	$v\lambda x^{v-1} \exp(-\lambda x^v)$	0	
Wishart	<code>dwish(R = R, df = k)</code> R $p \times p$ pos. def., $k \geq p$	$\frac{ x ^{(k-p-1)/2} R ^{k/2} \exp\{-\text{tr}(Rx/2)\}}{2^{pk/2} \Gamma_p(k/2)}$		

Alternative parameterizations for distributions

NIMBLE allows one to specify distributions in model code using a variety of parameterizations, including the BUGS parameterizations. Behind the scenes, NIMBLE uses a single parameterization (NIMBLE’s ‘canonical’ parameterization) when defining nodes and relationships between nodes and when doing calculations.

The full set of parameterizations that one can use in model code is listed in Table 5.2. To understand how NIMBLE handles alternative parameterizations, it is useful to distinguish three cases, using the `gamma` distribution as an example:

1. A *canonical* parameterization is used directly for computations. Usually this is the parameterization in the `Rmath` header of R’s C implementation of distributions. For `gamma`, this is (shape, scale).
2. The BUGS parameterization is the one defined in the original BUGS language. For `gamma`, this is (shape, rate).
3. An *alternative* parameterization is one that must be converted into the *canonical* parameterization. For example, NIMBLE provides a (mean, sd) parameterization and creates nodes to calculate (shape, scale) from (mean, sd). In the case of `gamma`, the BUGS parameterization is also an *alternative* parameterization.

Since NIMBLE provides compatibility with existing BUGS and JAGS code, the order of parameters places the BUGS parameterization first. For example, the order of parameters for `dgamma` is `dgamma(shape, rate, scale, mean, sd)`. Like R, if parameter names are not given, they are taken in order, so that (shape, rate) is the default. This happens to match R’s order of parameters, but it need not. If names are given, they can be given in any order. NIMBLE knows that rate is an alternative to scale and that (mean, sd) are an alternative to (shape, scale or rate).

Table 5.2: Distribution parameterizations allowed in NIMBLE. The first column indicates the supported parameterizations for distributions given in Table 5.1. The second column indicates the relationship to the *canonical* parameterization used in NIMBLE.

Parameterization	NIMBLE re-parameterization
dbern(prob)	dbin(size = 1, prob)
dbeta(shape1, shape2)	canonical
dbeta(mean, sd)	dbeta(shape1 = mean ² * (1-mean) / sd ² - mean, shape2 = mean * (1 - mean) ² / sd ² + mean - 1)
dbin(prob, size)	canonical
dcat(prob)	canonical
dchisq(df)	canonical
ddirch(alpha)	canonical
dexp(rate)	canonical
dexp(scale)	dexp(rate = 1/scale)
dgamma(shape, scale)	canonical
dgamma(shape, rate)	dgamma(shape, scale = 1 / rate)
dgamma(mean, sd)	dgamma(shape = mean ² /sd ² , scale = sd ² /mean)
dlogis(location, scale)	canonical
dlogis(location, rate)	dlogis(location, scale = 1 / rate)
dlnorm(meanlog, sdlog)	canonical
dlnorm(meanlog, tauog)	dlnorm(meanlog, sdlog = 1 / sqrt(tauog))
dlnorm(meanlog, varlog)	dlnorm(meanlog, sdlog = sqrt(varlog))
dmulti(prob, size)	canonical
dmnorm(mean, cholesky, prec_param=1)	canonical (precision)
dmnorm(mean, cholesky, prec_param=0)	canonical (covariance)
dmnorm(mean, prec)	dmnorm(mean, cholesky = chol(prec), prec_param=1)
dmnorm(mean, cov)	dmnorm(mean, cholesky = chol(cov), prec_param=0)
dnegbin(prob, size)	canonical
dnorm(mean, sd)	canonical
dnorm(mean, tau)	dnorm(mean, sd = 1 / sqrt(var))
dnorm(mean, var)	dnorm(mean, sd = sqrt(var))
dpois(lambda)	canonical
dt(mu, sigma, df)	canonical
dt(mu, tau, df)	dt(mu, sigma = 1 / sqrt(tau), df)
dt(mu, sigma2, df)	dt(mu, sigma = sqrt(sigma2), df)
dunif(min, max)	canonical
dweib(shape, scale)	canonical
dweib(shape, rate)	dweib(shape, scale = 1 / rate)
dweib(shape, lambda)	dweib(shape, scale = lambda ^(- 1 / shape))
dwish(R, df)	dwish(cholesky = chol(R), df, scale_param = 0)
dwish(S, df)	dwish(cholesky = chol(S), df, scale_param = 1)

Note that for multivariate normal and Wishart, the canonical parameterization uses the Cholesky decomposition of either of the precision or covariance matrix. In some cases it may be more efficient to use that parameterization directly. If `prec_param` is TRUE, the `cholesky` argument is treated as the Cholesky decomposition of a precision matrix. Otherwise it is treated as the Cholesky decomposition of a covariance matrix.

In addition, we provide alternative distribution names, known as aliases, as in JAGS, as specified in Table 5.3.

Distribution	Canonical name	Alias
Binomial	<code>dbin</code>	<code>dbinom</code>
Chi-square	<code>dchisq</code>	<code>dchisqr</code>
Dirichlet	<code>ddirch</code>	<code>ddirich</code>
Multinomial	<code>dmulti</code>	<code>dmultinom</code>
Negative binomial	<code>dnegbin</code>	<code>dnbinom</code>
Weibull	<code>dweib</code>	<code>dweibull</code>
Wishart	<code>dwish</code>	<code>dwishart</code>

Table 5.3: Distributions with alternative names (aliases).

We plan to, but do not currently, include the following distributions as part of core NIMBLE: double exponential (Laplace), beta-binomial, Dirichlet-multinomial, F, inverse gamma, Pareto, inverse Wishart, and various forms of multivariate t.

5.2.3 Available BUGS language functions

Tables 5.4-5.5 show the available operators and functions. These are also available for `nimbleFunction` programming (see Chapter 9). In fact, BUGS model nodes are implemented as `nimbleFunctions` that are custom-generated from BUGS declarations, so it would be more correct to say that functions and operators available for `nimbleFunctions` are also available for the model declarations.

For the most part NIMBLE supports the functions used in BUGS and JAGS, with exceptions indicated in the table. Additional functions provided by NIMBLE are also listed. Note that we provide distribution functions for use in calculations, namely the “p”, “q”, and “d” functions. See Section 9.5.19 for details on the syntax for using distribution functions, as only some parameterizations are allowed and the names of some distributions differ from those used to define nodes in a model.

Table 5.4: Functions operating on scalars, many of which can operate on each element (component-wise) of vectors and matrices. Status column indicates if the function is currently provided in NIMBLE.

Usage	Description	Comments	Status	Accepts vector input
<code>x y, x & y</code>	logical OR () and AND(&)		✓	
<code>!x</code>	logical not		✓	
<code>x > y, x >= y</code>	greater than (and or equal to)		✓	
<code>x < y, x <= y</code>	less than (and or equal to)		✓	
<code>x != y, x == y</code>	(not) equals		✓	
<code>x + y, x - y, x * y</code>	component-wise operators	mix of scalar and vector ok	✓	✓
<code>x / y,</code>	component-wise division	vector x and scalar y ok	✓	✓
<code>x^y, pow(x, y)</code>	power	x^y ; vector x and scalar y ok	✓	✓
<code>x %% y</code>	modulo (remainder)		✓	
<code>min(x1, x2), max(x1, x2)</code>	min. (max.) of two scalars		✓	
<code>exp(x)</code>	exponential		✓	✓
<code>log(x)</code>	natural logarithm		✓	✓
<code>sqrt(x)</code>	square root		✓	✓
<code>abs(x)</code>	absolute value		✓	✓
<code>step(x)</code>	step function at 0	0 if $x < 0$, 1 if $x > 0$	✓	✓
<code>equals(x, y)</code>	equality of two scalars	1 if $x == y$, 0 if $x != y$	✓	
<code>cube(x)</code>	third power	x^3	✓	✓
<code>sin(x), cos(x), tan(x)</code>	trigonometric functions		✓	✓
<code>asin(x), acos(x), atan(x)</code>	inverse trigonometric functions		✓	✓
<code>asinh(x), acosh(x), atanh(x)</code>	inv. hyperbolic trig. functions		✓	✓
<code>logit(x)</code>	logit	$\log(x/(1-x))$	✓	✓
<code>ilogit(x), expit(x)</code>	inverse logit	$\exp(x)/(1+\exp(x))$	✓	✓
<code>probit(x)</code>	probit (Gaussian quantile)	$\Phi^{-1}(x)$	✓	✓
<code>iprobit(x), phi(x)</code>	inverse probit (Gaussian CDF)	$\Phi(x)$	✓	✓

Table 5.4: Functions operating on scalars, many of which can operate on each element (component-wise) of vectors and matrices. Status column indicates if the function is currently provided in NIMBLE.

Usage	Description	Comments	Status	Accepts vector input
<code>cloglog(x)</code>	complementary log log	$\log(-\log(1-x))$	✓	✓
<code>icloglog(x)</code>	inverse complementary log log	$1 - \exp(-\exp(x))$	✓	✓
<code>ceiling(x)</code>	ceiling function	$\lceil x \rceil$	✓	✓
<code>floor(x)</code>	floor function	$\lfloor x \rfloor$	✓	✓
<code>round(x)</code>	round to integer		✓	✓
<code>trunc(x)</code>	truncation to integer		✓	✓
<code>lgamma(x)</code> , <code>loggam(x)</code>	log gamma function	$\log \Gamma(x)$	✓	✓
<code>log1p(x)</code>	log of 1 + x	$\log(1+x)$	✓	✓
<code>lfactorial(x)</code> , <code>logfact(x)</code>	log factorial	$\log x!$	✓	✓
<code>log1p(x)</code>	log one-plus	$\log(x+1)$	✓	✓
<code>qDIST(x, PARAMS)</code>	“q” distribution functions	canonical parameterization	✓	
<code>pDIST(x, PARAMS)</code>	“p” distribution functions	canonical parameterization	✓	
<code>rDIST(1, PARAMS)</code>	“r” distribution functions	canonical parameterization	✓	
<code>dDIST(x, PARAMS)</code>	“d” distribution functions	canonical parameterization	✓	
<code>sort(x)</code>				
<code>rank(x, s)</code>				
<code>ranked(x, s)</code>				
<code>order(x)</code>				

Table 5.5: Functions operating on vectors and matrices. Status column indicates if the function is currently provided in NIMBLE.

Usage	Description	Comments	Status
<code>inverse(x)</code>	matrix inverse	\mathbf{x} symmetric, positive definite	✓
<code>chol(x)</code>	matrix Cholesky factorization	\mathbf{x} symmetric, positive definite	✓
<code>eigen(x)</code>	matrix eigendecomposition		
<code>svd(x)</code>	matrix singular value decomposition		
<code>t(x)</code>	matrix transpose	x^\top	✓
<code>x%*%y</code>	matrix multiply	xy ; x, y conformant	✓
<code>inprod(x, y)</code>	dot product	$x^\top y$; \mathbf{x} and \mathbf{y} vectors	✓
<code>logdet(x)</code>	log matrix determinant	$\log x $	✓
<code>asRow(x)</code>	convert vector \mathbf{x} to 1-row matrix	sometimes automatic	✓
<code>asCol(x)</code>	convert vector \mathbf{x} to 1-column matrix	sometimes automatic	✓
<code>sum(x)</code>	sum of elements of \mathbf{x}		✓
<code>mean(x)</code>	mean of elements of \mathbf{x}		✓
<code>sd(x)</code>	standard deviation of elements of \mathbf{x}		✓
<code>prod(x)</code>	product of elements of \mathbf{x}		✓
<code>min(x)</code> , <code>max(x)</code>	min. (max.) of elements of \mathbf{x}		✓
<code>pmin(x, y)</code> , <code>pmax(x, y)</code>	vector of mins (maxs) of elements of \mathbf{x} and \mathbf{y}		✓
<code>interp.lin(x, v1, v2)</code>	linear interpolation		

5.2.4 Available link functions

NIMBLE allows the link functions listed in Table 5.6.

Table 5.6: Link functions

Link function	Description	Range	Inverse
<code>cloglog(y) <- x</code>	Complementary log log	$0 < y < 1$	<code>y <- icloglog(x)</code>
<code>log(y) <- x</code>	Log	$0 < y$	<code>y <- exp(x)</code>
<code>logit(y) <- x</code>	Logit	$0 < y < 1$	<code>y <- expit(x)</code>
<code>probit(y) <- x</code>	Probit	$0 < y < 1$	<code>y <- iprobit(x)</code>

Link functions are specified as functions applied to a variable on the left hand side of a BUGS expression. To handle link functions, NIMBLE does some processing that inserts an additional node into the model. For example, the declaration `logit(p[i]) ~ dnorm(mu[i], 1)`, is equivalent to the follow two declarations:

- `logit_p[i] ~ dnorm(mu[i], 1)`,
- `p[i] <- expit(logit_p[i])`

where `expit` is the inverse of `logit`. When the BUGS expression defines a deterministic node, such as `logit(p) <- b0 + b1*x`, the same operations are performed except that `logit_p` is a deterministic node.

Note that we do not provide an automatic way of initializing the additional node (`logit_p` in this case), which is a parent node of the explicit node (`p[i]`), without explicitly referring to the additional node by the name that NIMBLE generates. For deterministic declarations, this is of little import, but for stochastic declarations, it requires care.

5.2.5 Adding user-defined distributions and functions

As of Version 0.4, NIMBLE allows you to define your own functions and distributions as `nimbleFunctions` for use in BUGS code. As a result, NIMBLE frees you from being constrained to the functions and distributions just discussed. For example, instead of setting up a Dirichlet prior with multinomial data and needing to use MCMC, one could recognize that this results in a Dirichlet-multinomial distribution and provide that as a user-defined distribution instead.

Further, while NIMBLE at the moment does not allow the use of random indices, such as is common in clustering contexts, you may be able to analytically integrate over the random indices, resulting in a mixture distribution that you could implement as a user-defined distribution. For example, one could implement the `dnormmix` distribution provided in JAGS as a user-defined distribution in NIMBLE.

User-defined functions

To provide a new function for use in BUGS code, simply create a `nimbleFunction` that has no `setup` code. Then use it in your BUGS code. That's it.

Writing `nimbleFunctions` requires that you declare the dimensionality of arguments and the returned object (Section 9.5.2). Make sure that the dimensionality specified in your `nimbleFunction` matches how you use it in BUGS code. For example, if you define scalar parameters in your BUGS code you will want to define `nimbleFunctions` that take scalar arguments. Here is an example that returns twice its input argument:

```
timesTwo <- nimbleFunction(
  run = function(x = double(0)) {
    returnType(double(0))
    return(2*x)
  })

code <- BUGScode({
  for(i in 1:3) {
    mu[i] ~ dnorm(0, 1)
    mu_times_two[i] <- timesTwo(mu[i])
  }
})
```

The `x = double(0)` argument and `returnType(double(0))` establish that the input and output will both be 0-dimensional (scalar) numbers.

You can define `nimbleFunctions` that take inputs and outputs with more dimensions. Here is an example that takes a vector (1-dimensional) as input and returns a vector with twice the input values:

```
vectorTimesTwo <- nimbleFunction(
  run = function(x = double(1)) {
    returnType(double(1))
    return(2*x)
  }
)

code <- BUGScode({
  for(i in 1:3) {
    mu[i] ~ dnorm(0, 1)
  }
  mu_times_two[1:3] <- vectorTimesTwo(mu[1:3])
})
```

There is a subtle difference between the `mu_times_two` variables in the two examples. In the first example, there are individual nodes for each `mu_times_two[i]`. In the second example, there is a single multivariate node, `mu_times_two[1:3]`. Each implementation could

be more efficient for different needs. For example, suppose an algorithm modifies the value of `mu[2]` and then updates nodes that depend on it. In the first example, `mu_times_two[2]` would be updated. In the second example `mu_times_two[1:3]` would be updated because it is a single, vector node.

At present you cannot provide a scalar argument where a `nimbleFunction` expects a vector; unlike in R, scalars are not simply vectors of length 1.

User-defined distributions

To provide a user-defined distribution, you need to do the following:

1. define density (“d”) and simulation (“r”) `nimbleFunctions`, without setup code, for your distribution,
2. register the distribution using `registerDistributions`, and
3. use your distribution in BUGS code.

You can optionally provide distribution (“p”) and quantile (“q”) functions, which will allow truncation to be applied to a user-defined distribution. You can also provide a list of alternative parameterizations.

Here is an extended example of providing a univariate exponential distribution (although this is already provided by NIMBLE) and a multivariate Dirichlet-multinomial distribution.

```
dmyexp <- nimbleFunction(
  run = function(x = double(0), rate = double(0, default = 1),
    log = integer(0, default = 0)) {
    returnType(double(0))
    logProb <- log(rate) - x*rate
    if(log) return(logProb)
    else return(exp(logProb))
  })

rmyexp <- nimbleFunction(
  run = function(n = integer(0), rate = double(0, default = 1)) {
    returnType(double(0))
    if(n != 1) print("rmyexp only allows n = 1; using n = 1.")
    dev <- runif(1, 0, 1)
    return(-log(1-dev) / rate)
  })

pmyexp <- nimbleFunction(
  run = function(q = double(0), rate = double(0, default = 1),
    lower.tail = integer(0, default = 1),
    log.p = integer(0, default = 0)) {
    returnType(double(0))
    if(!lower.tail) {
      logp <- -rate * q
```

```

        if(log.p) return(logp)
        else return(exp(logp))
    } else {
        p <- 1 - exp(-rate * q)
        if(!log.p) return(p)
        else return(log(p))
    }
})

qmyexp <- nimbleFunction(
  run = function(p = double(0), rate = double(0, default = 1),
    lower.tail = integer(0, default = 1),
    log.p = integer(0, default = 0)) {
    returnType(double(0))
    if(log.p) p <- exp(p)
    if(!lower.tail) p <- 1 - p
    return(-log(1 - p) / rate)
  })

ddirchmulti <- nimbleFunction(
  run = function(x = double(1), alpha = double(1), size = double(0),
    log = integer(0)) {
    returnType(double(0))
    logProb <- lgamma(sum(alpha)) - sum(lgamma(alpha)) + sum(lgamma(alpha + x))
    - lgamma(sum(alpha) + size)
    if(log) return(logProb)
    else return(exp(logProb))
  })

rdirchmulti <- nimbleFunction(
  run = function(n = integer(0), alpha = double(1), size = double(0)) {
    returnType(double(1))
    if(n != 1) print("rdirchmulti only allows n = 1; using n = 1.")
    p <- rdirch(1, alpha)
    return(rmulti(1, size = size, prob = p))
  })

registerDistributions(list(
  dmyexp = list(
    BUGSdist = "dmyexp(rate, scale)",
    Rdist = "dmyexp(rate = 1/scale)",
    altParams = c("scale = 1/rate", "mean = 1/rate"),
    pqAvail = TRUE,
    range = c(0, Inf)
  )

```

```

    ),
    ddirchmulti = list(
      BUGSdist = "ddirchmulti(alpha, size)",
      types = c('value = double(1)', 'alpha = double(1)'),
    )
  ))

code <- BUGScode({
  y[1:K] ~ ddirchmulti(alpha[1:K], n)
  for(i in 1:K) {
    alpha[i] ~ T(dmyexp(scale = 3), 0, 100)
  }
})

```

The distribution-related functions should take as input the parameters for a single parameterization, which will be the canonical parameterization that NIMBLE will use. If you would like to allow for multiple parameterizations, you can do this via the `Rdist` element of the list provided to `registerDistributions` as illustrated. If you provide CDF (“p”) and inverse CDF (quantile, i.e. “q”) functions, be sure to specify `pqAvail = TRUE` when you call `registerDistributions`.

Here are more details on the requirements for distribution-related `nimbleFunctions`, which follow R’s conventions:

- Your distribution-related functions must have names that begin with “d”, “r”, “p” and “q”. The name of the distribution must not be identical to any of the NIMBLE-provided distributions.
- The function name in the `BUGSdist` entry in the list provided to `registerDistributions` will be the name you can use in BUGS code.
- The name of your `nimbleFunctions` must match the function name in the `Rdist` entry. If missing, the `Rdist` entry defaults to be the same as the `BUGSdist` entry.
- All simulation (“r”) functions must take `n` as their first argument. Note that you may simply have your function only handle `n=1` and return an warning for other values of `n`.
- Your distribution-related functions must take as arguments the parameters in default order, starting as the second argument and in the order used in the parameterizations in the `Rdist` argument to `registerDistributions` or the `BUGSdist` argument if there are no alternative parameterizations. NIMBLE uses doubles for numerical calculations, so we suggest simply using doubles in general, even for integer-valued parameters or values of random variables.
- All density functions must have as their last argument `log` and implement return of the log probability density. NIMBLE algorithms typically use only `log = 1`, but we recommend you implement the `log = 0` case for completeness.
- All distribution and quantile functions must have their last two arguments be (in order) `lower.tail` and `log.p`. These functions must work for `lower.tail = 1` (i.e., `TRUE`) and `log.p = 0` (i.e., `FALSE`), as these are the inputs we use when working

with truncated distributions. It is your choice whether you implement the necessary calculations for other combinations of these inputs, but again we recommend doing so for completeness.

- Define the `nimbleFunctions` in R’s global environment. Don’t expect R’s standard scoping to work⁵.

Further details on using `registerDistributions` can be found via `help(registerDistributions)`. NIMBLE uses the same list format as `registerDistributions` to define its distributions. This list can be found in the `R/distributions_inputList.R` file in the package source code directory.

5.2.6 Data and constants

NIMBLE makes a distinction between data and constants that would both be considered “data” in BUGS and JAGS.

- *Constants* can never be changed and must be provided when a model is defined. For example, a vector of known index values, such as for block indices, helps define the model graph itself and must be provided as constants. Variables used in the index ranges of for-loops must also be provided as constants.
- *Data* is a label for the role a node plays in the model. Nodes marked as data will by default be protected from any functions that would simulate over their values (see `simulate` in Chapter 9), but it is possible to over-ride that default or to change their values by direct assignment. This allows an algorithm to be applied to many data sets in the same model without re-creating the model each time. It also allows simulation of data in a model.

We encourage users to distinguish between data and constants when building a model via `nimbleModel`. However, for compatibility with BUGS and JAGS, NIMBLE allows both to be provided in the `constants` argument to `nimbleModel`, in which case NIMBLE determines which are which, based on which variables appear on the left-hand side of BUGS declarations.

It is also possible to have variables appear only on the right-hand side of BUGS declarations (e.g., covariates/predictors). If the values of these variables will never change, one can specify these via `constants`. However, one might want to define a model and then change such values (e.g., use a model with different covariate values). Therefore one can provide the values of such variables via the `data` argument to `nimbleModel` and these will appear as variables in the model but will not have any corresponding nodes. A user can change these values via direct assignment if desired.

Missing data values

Sometimes one needs a model variable to have a mix of data and non-data, often due to missing data values. In NIMBLE, when data values are provided, any nodes with NA values

⁵NIMBLE can’t use R’s standard scoping because it doesn’t work for R reference classes, and `nimbleFunctions` are implemented as custom-generated reference classes.

will *not* be labeled as data. The result will be that nodes with non-NA values will be flagged as data nodes, while nodes with NA values will not. A node following a multivariate distribution must be either entirely observed or entirely missing.

Here's an example of running an MCMC on the *pump* model, with two of the observations taken to be missing. Some of the steps in this example are documented more below. NIMBLE's default MCMC specification will treat the missing values as unknowns to be sampled, as can be seen in the MCMC output here.

```
pumpMiss <- pump$newModel()
pumpMiss$resetData()
pumpDataNew <- pumpData
pumpDataNew$x[c(1, 3)] <- NA
pumpMiss$setData(pumpDataNew)

pumpMissSpec <- configureMCMC(pumpMiss)
pumpMissSpec$addMonitors(c('x', 'alpha', 'beta', 'theta'))

pumpMissMCMC <- buildMCMC(pumpMissSpec)
Cobj <- compileNimble(pumpMiss, pumpMissMCMC)

niter <- 1000
set.seed(0)
Cobj$pumpMissMCMC$run(niter)
samples <- as.matrix(Cobj$pumpMissMCMC$mvSamples)

samples[1:5, 13:17]
```

Missing values may also occur in variables appearing on the right-hand side of BUGS declarations. Values for such variables should be passed in via the `data` argument to `nimbleModel`, with NA for the missing values. In many contexts, one would want to specify (prior) distributions for the elements with missing values.

5.2.7 Defining alternative models with the same code

Avoiding code duplication is a basic principle of good programming. In BUGS and JAGS, if one wants to consider model variants, one needs to create complete model code for each one. This can lead to lots of code and potential errors.

In NIMBLE, one can use definition-time if-then-else statements to create different models from the same code. As a simple example, say we have a linear regression model and want to consider including or omitting `x[2]` as an explanatory variable:

```
regressionCode <- nimbleCode({
  intercept ~ dnorm(0, sd = 1000)
  slope1 ~ dnorm(0, sd = 1000)
  if(includeX2) {
```

```

    slope2 ~ dnorm(0, sd = 1000)
    for(i in 1:N)
      predictedY[i] <- intercept + slope1 * x1[i] + slope2 * x2[i]
  } else {
    for(i in 1:N) predictedY[i] <- intercept + slope1 * x1[i]
  }
  sigmaY ~ dunif(0, 100)
  for(i in 1:N) Y[i] ~ dnorm(predictedY[i], sigmaY)
})

includeX2 <- FALSE
modelWithoutX2 <- nimbleModel(regressionCode, constants = list(N = 30),
                             check=FALSE)

## defining model...
## building model...
## model building finished

modelWithoutX2$getVarNames()

## [1] "intercept"
## [2] "slope1"
## [3] "predictedY"
## [4] "sigmaY"
## [5] "lifted_d1_over_sqrt_oPsigmaY_cP"
## [6] "Y"
## [7] "x1"

includeX2 <- TRUE
modelWithX2 <- nimbleModel(regressionCode, constants = list(N = 30),
                           check = FALSE)

## defining model...
## building model...
## model building finished

modelWithX2$getVarNames()

## [1] "intercept"
## [2] "slope1"
## [3] "slope2"
## [4] "predictedY"
## [5] "sigmaY"
## [6] "lifted_d1_over_sqrt_oPsigmaY_cP"
## [7] "Y"
## [8] "x1"
## [9] "x2"

```

5.2.8 Truncation, censoring, and constraints

NIMBLE provides three ways to declare boundaries on the value of a variable, each for different situations. We introduce these and comment on their relationships to related features of JAGS and BUGS. The three methods are:

Truncation

Either of the following forms,

- $x \sim \text{dnorm}(0, \text{sd} = 10) \text{ T}(0, a)$, or
- $x \sim \text{T}(\text{dnorm}(0, \text{sd} = 10), 0, a)$,

declares that x follows a normal distribution between 0 and a . Either boundary may be omitted or may be another node, such as a in this example. The first form is compatible with JAGS, but in NIMBLE it can only be used when reading code from a text file. When writing model code in R, the second version must be used.

Truncation means the possible values of x are limited a priori, hence the probability density of x must be normalized. In this example it would be the normal probability density divided by its integral from 0 to a ⁶. Like JAGS, NIMBLE also provides I as a synonym for T to accommodate older BUGS code, but T is preferred because it disambiguates multiple usages of I in BUGS.

As in JAGS, $\mu \sim \text{dfoo}(\text{theta}) \text{ T}(L, U)$ restricts X to lie in $[L, U]$ (i.e., inclusive of L and U).

Censoring

Censoring refers to the situation where one datum gives the lower or upper bound on an unobserved random variable. This is common in survival analysis, when for individuals still surviving at the end of a study, their age of death is not known and hence is “censored” (right-censoring). NIMBLE adopts JAGS syntax for censoring, as follows (using right-censoring as an example):

```
censored[i] ~ dinterval(t[i], c[i])
t[i] ~ dweib(r, mu[i])
```

where `censored[i]` should be given as data with a value of 1 if `t[i]` is right-censored (`t[i] > c[i]`) and 0 if it is observed. The data vector for `t` should have NA (indicating missing data) for any censored `t[i]` entries. (As a result, these nodes will be sampled in an MCMC.) The data vector for `c` should give the censoring times corresponding to censored entries and a value below the observed times for uncensored entries (e.g., 0 (assuming `t[i] > 0`)). Left-censoring would be specified by setting `censored[i]` to 0 and `t[i]` to NA.

The `dinterval` is not really a distribution but rather a trick: in the above example when `censored[i] = 1` it gives a “probability” of 1 if `t[i] > c[i]` and 0 otherwise. This

⁶If you have a model object `model`, you can see exactly the calculation used by typing `model$nodes[['x']]$calculate`

means that $t[i] \leq c[i]$ is treated as impossible. More generally than simple right- or left-censoring, `censored[i] ~ dinterval(t[i], c[i,])` is defined such that for a vector of increasing cutpoints, `c[i,]`, `t[i]` is enforced to fall within the `censored[i]`-th cutpoint interval. This is done by setting data `censored[i]` as follows:

```

censored[i] = 0 if t[i] ≤ c[i, 1]
censored[i] = m if c[i, m] < t[i] ≤ c[i, m+1] for 1 ≤ m ≤ M
censored[i] = M if c[i, M] < t[i].

```

(The `i` index is provided only for consistency with the previous example.) The most common uses of `dinterval` will be for left- and right-censored data, in which case `c[i,]` will be a single value (and typically given as simply `c[i]`), and for interval-censored data, in which case `c[i,]` will be a vector of two values.

Nodes following a `dinterval` distribution should normally be set as `data` with known values. Otherwise, the node may simulated during initialization in some algorithms (e.g., MCMC) and thereby establish a permanent, perhaps unintended, constraint.

Censoring differs from truncation because censoring an observation involves bounds on a random variable that could have taken any value, while in truncation we know a priori that a datum could not have occurred outside the truncation range.

Constraints and ordering

NIMBLE provides a more general way to enforce constraints using `dconstraint(cond)`. For example, we could specify that the sum of `mu1` and `mu2` must be positive like this:

```

mu1 ~ dnorm(0, 1)
mu2 ~ dnorm(0, 1)
constraint_data ~ dconstraint( mu1 + mu2 > 0 )

```

with `constraint_data` set (as `data`) to 1. This is equivalent to a half-normal distribution on the half-plane $\mu_1 + \mu_2 > 0$. However, note that this equivalence only holds when conditioning on `constraint_data` (e.g., in an MCMC) and not when simulating from the model using `simulate`. Nodes following `dconstraint` should be provided as data for the same reason of avoiding unintended initialization described above for `dinterval`.

Formally, `dconstraint(condition)` is a probability distribution on $\{0, 1\}$ such that $P(1) = 1$ if `cond` is `TRUE` and $P(0) = 1$ if `cond` is `FALSE`.

Of course, in many cases, parameterizing the model so that the constraints are automatically respected may be a better strategy than using `dconstraint`. One should be cautious about constraints that would make it hard for an MCMC or optimization to move through the parameter space (such as equality constraints that involve two or more parameters). For such restrictive constraints, general purpose algorithms that are not tailored to the constraints may fail or be inefficient. If constraints are used, it will generally be wise to ensure the model is initialized with values that satisfy them.

Ordering To specify an ordering of parameters, such as $\alpha_1 \leq \alpha_2 \leq \alpha_3$ one can use `dconstraint` as follows:

```
constraint_data ~ dconstraint( alpha1 <= alpha2 & alpha2 <= alpha3 )
```

Note that unlike in BUGS, one cannot specify prior ordering using syntax such as

```
alpha[1] ~ dnorm(0, 1) I(, alpha[2])
alpha[2] ~ dnorm(0, 1) I(alpha[1], alpha[3])
alpha[3] ~ dnorm(0, 1) I(alpha[2], )
```

as this does not represent a directed acyclic graph.

Also note that specifying prior ordering using `T(,)` can result in possibly unexpected results. For example:

```
alpha1 ~ dnorm(0, 1)
alpha2 ~ dnorm(0, 1) T(alpha1, )
alpha3 ~ dnorm(0, 1) T(alpha2, )
```

will enforce $\alpha_1 \leq \alpha_2 \leq \alpha_3$, but it does not treat the three parameters symmetrically. Instead it puts a marginal prior on `alpha1` that is standard normal and then constrains `alpha2` and `alpha3` to follow truncated normal distributions. This is not equivalent to a symmetric prior on the three `alphas` that assigns 0 probability density when values are not in order.

NIMBLE does not support the JAGS `sort` syntax.

5.2.9 Understanding lifted nodes

In some cases, NIMBLE introduces new nodes into the model that were not specified in the BUGS code for the model, such as the `lifted_d1_over_beta` node in the introductory example. For this reason, it is important that programs written to adapt to different model structures use NIMBLE's systems for querying the model graph. For example, a call to `pump$getDependencies("beta")` will correctly include `lifted_d1_over_beta` in the results. If one skips this step and assumes the nodes are only those that appear in the BUGS code, one may not get correct results.

It can be helpful to know the situations in which lifted nodes are generated. These include:

- When distribution parameters are expressions, NIMBLE creates a new deterministic node that contains the expression for a given parameter. The node is then a direct descendant of the new deterministic node. This is an optional feature, but it is currently enabled in all cases.
- As discussed in Section 5.2.4 the use of link functions causes new nodes to be introduced. This requires care if you need to initialize values in stochastic declarations with link functions.

- Use of alternative parameterizations of distributions, described in Section 5.2.2. For example when a user provides the precision of a normal distribution as `tau`, NIMBLE creates a new node `sd <- 1/sqrt(tau)` and uses `sd` as a parameter in the normal distribution. If many nodes use the same `tau`, only one new `sd` node will be created, so the computation `1/sqrt(tau)` will not be repeated redundantly.

5.3 Creating model objects

NIMBLE provides two functions for creating model objects: `nimbleModel` and `readBUGSmodel`. The first, `nimbleModel`, is the primary way to create models and was illustrated in Chapter 2. The second, `readBUGSmodel` provides compatibility with BUGS file formats for models, variables, data, and initial values for MCMC.

NIMBLE also provides some additional flexibility in setting data in a model and in defining multiple models from the same model definition, as described at the end of this section.

5.3.1 Using `nimbleModel` to specify a model

The R help page (`?nimbleModel`) provides more details on `nimbleModel` arguments.

5.3.2 Specifying a model from standard BUGS and JAGS input files

Users with BUGS and JAGS experience may have files set up in standard formats for use in BUGS and JAGS. `readBUGSmodel` can read in the model, data/constant values and initial values in those formats. It can also take information directly from R objects somewhat more flexibly than `nimbleModel`, specifically allowing inputs set up similarly to those for BUGS and JAGS. In either case, after processing the inputs, it calls `nimbleModel`. Note that unlike BUGS and JAGS, only a single set of initial values can be specified in creating a model. Please see `help(readBUGSmodel)` for argument details.

As an example of using `readBUGSmodel`, let's create a model for the *pump* example from BUGS.

```
pumpDir <- system.file('classic-bugs', 'vol1', 'pump', package = 'nimble')
pumpModel <- readBUGSmodel('pump.bug', data = 'pump-data.R',
                           inits = 'pump-init.R', dir = pumpDir)

## defining model...
## Detected x as data within 'constants'.
## Adding x as data for building model.

## building model...
## setting data and initial values...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)
## model building finished
```

Note that `readBUGSmodel` allows one to include `var` and `data` blocks in the model file as in some of the BUGS examples (such as `inhaler`). The `data` block pre-computes constant and data values. Also note that if `data` and `inits` are provided as files, the files should contain R code that creates objects analogous to what would populate the list if a list were provided instead. Please see the JAGS manual examples or the `classic_bugs` directory in the NIMBLE package for example syntax. NIMBLE by and large does not need the information given in a `var` block but occasionally this is used to determine dimensionality, such as in the case of syntax like `xbar <- mean(x[])` where `x` is a variable that appears only on the right-hand side of BUGS expressions.

Note that NIMBLE does not handle formatting such as in some of the original BUGS examples in which data was indicated with syntax such as `data x in 'x.txt'`.

5.3.3 Providing data via `setData`

Whereas the *constants* are a property of the *model definition* – since they may help determine the model structure itself – *data* nodes can be different in different copies of the model generated from the same *model definition*. For this reason, *data* is not required to be provided when the model code is processed. It can be provided later via the model member function `setData`. e.g., `pump$setData(pumpData)`, where `pumpData` is a named list of data values.

`setData` does two things: it sets the values of the data nodes, and it flags those nodes as containing data. `nimbleFunction` programmers can then use that information to control whether an algorithm should over-write data or not. For example, NIMBLE's `simulate` functions by default do not overwrite data values but can be told to do so. Values of data variables can be replaced, and the indication of which nodes should be treated as data can be reset by using the `resetData` method, e.g. `pump$resetData()`.

5.3.4 Making multiple instances from the same model definition

Sometimes it is useful to have more than one copy of the same model. For example, `nimbleFunctions` are often bound to a particular model as a result of `setup` code. A user could build multiple algorithms to use the same model instance, or they may want each algorithm to have its own instance of the model.

There are two ways to create new instances of a model, shown in this example:

```
simpleCode <- nimbleCode({
  for(i in 1:N) x[i] ~ dnorm(0, 1)
})

## Return the model definition only, not a built model
simpleModelDefinition <- nimbleModel(simpleCode, constants = list(N = 10),
                                   returnDef = TRUE, check = FALSE)

## defining model...

## Make one instance of the model
```

```
simpleModelCopy1 <- simpleModelDefinition$newModel(check = FALSE)
## Make another instance from the same definition
simpleModelCopy2 <- simpleModelDefinition$newModel(check = FALSE)
## Ask simpleModelCopy2 for another copy of itself
simpleModelCopy3 <- simpleModelCopy2$newModel(check = FALSE)
```

Each copy of the model can have different nodes flagged as data and different values in any nodes. They cannot have different values of N because that is a constant; it must be a constant because it helps define the model.

Chapter 6

Using NIMBLE models from R

6.1 Some basic concepts and terminology

Before going further, we need some basic concepts and terminology to be able to speak about NIMBLE clearly.

Say we have the following BUGS code

```
mc <- nimbleCode({
  a ~ dnorm(0, 0.001)
  for(i in 1:5) {
    y[i] ~ dnorm(a, 0.1)
    for(j in 1:3)
      z[i,j] ~ dnorm(y[i], sd = 0.1)
  }
  y.squared[1:5] <- y[1:5]^2
})

model <- nimbleModel(mc, data = list(z = matrix(rnorm(15), nrow = 5)),
  check = FALSE)

## defining model...
## building model...
## setting data and initial values...
## model building finished
```

In NIMBLE terminology:

- The *variables* of this model are `a`, `y`, `z`, and `y.squared`.
- The *nodes* of this model are `a`, `y[1] ... y[5]`, `z[1,1] ... z[5, 3]`, and `y.squared[1:5]`. In graph terminology, nodes are vertices in the model graph.
- the *node functions* of this model are `a ~ dnorm(0, 0.001)`, `y[i] ~ dnorm(a, 0.1)`, `z[i,j] ~ dnorm(y[i], sd = 0.1)`, and `y.squared[1:5] <- y[1:5]^2`. Each node has a corresponding node function. Sometimes the distinction between nodes and node

functions is important, but when it is not important we may refer to both simply as *nodes*.

- The *scalar elements* of this model include all the scalar nodes as well as the scalar elements `y.squared[1] ... y.squared[5]` of the multivariate node `y.squared[1:5]`.

6.2 Accessing variables

Model variables can be accessed and set just as in R using `$` and `[[]]`. For example

```
model$a <- 5
model$a
## [1] 5

model[['a']]
## [1] 5

model$y[2:4] <- rnorm(3)
model$y
## [1]          NA -0.6545846  1.7672873  0.7167075          NA

model[['y']][c(1, 5)] <- rnorm(2)
model$y
## [1]  0.9101742 -0.6545846  1.7672873  0.7167075  0.3841854

model$z[1,]
## [1]  0.2670988  1.5868335 -0.4734006
```

6.2.1 Accessing log probabilities via logProb variables

For each variable that contains at least one stochastic node, NIMBLE generates a model variable with the prefix “logProb_”. When the stochastic node is scalar, the `logProb` variable will have the same size. For example:

```
model$logProb_y
## [1] NA NA NA NA NA

calculate(model, 'y')
## [1] -15.29134
```

```
model$logProb_y
## [1] -2.906565 -3.668947 -2.592753 -2.987561 -3.135518
```

Creation of `logProb` variables for stochastic multivariate nodes is trickier, because they can represent an arbitrary block of a larger variable. In general NIMBLE records the `logProb` values using the lowest possible indices. For example, if `x[5:10, 15:20]` follows a Wishart distribution, its log probability (density) value will be stored in `logProb_x[5, 15]`. When possible, NIMBLE will reduce the dimensions of the corresponding `logProb` variable. For example, in

```
for(i in 1:10) x[i,] ~ dmnorm(mu[], prec[,])
```

`x` may be 10×20 (dimensions must be provided), but `logProb_x` will be 10×1 . For the most part you do not need to worry about how NIMBLE is storing the log probability values, because you can always get them using `getLogProb`.

6.3 Accessing nodes

While nodes that are part of a variable can be accessed as above, each node also has its own name that can be used to access it directly. For example, `y[2]` has the name “`y[2]`” and can be accessed by that name as follows:

```
model[['y[2]']]
## [1] -0.6545846

model[['y[2]']] <- -5
model$y
## [1] 0.9101742 -5.0000000 1.7672873 0.7167075 0.3841854

model[['z[2, 3]']]
## [1] -0.6203667

model[['z[2:4, 1:2]']][1, 2]
## [1] 0.5584864

model$z[2, 2]
## [1] 0.5584864
```

Notice that node names can include index blocks, such as `model[['z[2:4, 1:2]']]`, and these are not strictly required to correspond to actual nodes. Such blocks can be subsequently sub-indexed in the regular R manner.

6.3.1 How nodes are named

Every node has a name that is a character string including its indices, with a space after every comma. For example, `X[1, 2, 3]` has the name “`X[1, 2, 3]`”. Nodes following multivariate distributions have names that include their index blocks. For example, a multivariate node for `X[6:10, 3]` has the name “`X[6:10, 3]`”.

The definitive source for node names in a model is `getNodeNames`, described below. For example

```
multiVarCode <- nimbleCode({
  X[1, 1:5] ~ dmnorm(mu[], cov[,])
  X[6:10, 3] ~ dmnorm(mu[], cov[,])
})

multiVarModel <- nimbleModel(multiVarCode, dimensions = list(mu = 5, cov = c(5,5)),
                             check = FALSE)

## defining model...
## building model...
## model building finished

multiVarModel$getNodeNames()

## [1] "lifted_chol_oPcov_oB1to5_1to5_cB_cP[1:5, 1:5]"
## [2] "X[1, 1:5]"
## [3] "X[6:10, 3]"
```

You can see one lifted node for the Cholesky decomposition of `cov`, and the two multivariate normal nodes.

In the event you need to ensure that a name is formatted correctly, you can use the `expandNodeNames` method. For example, to get the spaces correctly inserted into “`X[1,1:5]`”:

```
multiVarModel$expandNodeNames("X[1,1:5]")

## [1] "X[1, 1:5]"
```

Alternatively, for those inclined to R’s less commonly used features, a nice trick is to use its `parse` and `deparse` functions.

```
deparse(parse(text = "X[1,1:5]", keep.source = FALSE)[[1]])

## [1] "X[1, 1:5]"
```

The `keep.source = FALSE` makes `parse` more efficient.

6.3.2 Why use node names?

Syntax like `pump[["x[2, 3]"]]` may seem strange at first, because the natural habit of an R user would be `pump[["x"]][2,3]`. To see its utility, consider the example of writing the `nimbleFunction` given in Section 2.7. By giving every scalar node a name, even if it is part of a multivariate variable, one can write functions in R or NIMBLE that access any single node by a name, regardless of the dimensionality of the variable in which it is embedded. This is particularly useful for NIMBLE, which resolves how to access a particular node during the compilation process.

6.4 calculate, simulate, and getLogProb

The four basic ways to operate a model are to calculate nodes, simulate into nodes, get the log probabilities (or probability densities) that have already been calculated, and compare the log probability of a new value to that of an old value. In more detail:

calculate For a stochastic node, `calculate` determines the log probability value, stores it in the appropriate `logProb` variable, and returns it. For a deterministic node, `calculate` executes the deterministic calculation and returns 0.

simulate For a stochastic node, `simulate` generates a random draw. For deterministic nodes, `simulate` is equivalent to `calculate` without returning 0. `simulate` always returns `NULL` (or `void` in C++).

getLogProb `getLogProb` simply returns the most recently calculated log probability value, or 0 for a deterministic node.

calculateDiff `calculateDiff` is identical to `calculate`, but it returns the new log probability value minus the one that was previously stored. This is useful when one wants to change the value or values of node(s) in the model (e.g., by setting a value or `simulate`) and then determine the change in the log probability, such as needed for a Metropolis-Hastings acceptance probability.

There are two ways to access `calculate`, `calculateDiff`, `simulate`, and `getLogProb`. The primary way is via the functions with those names, which accept arbitrary collections of nodes as input. In that case, `calculate` and `getLogProb` return the sum of the log probabilities from each node, while `calculateDiff` returns the sum of the new values minus the old values. The other way is to directly access the corresponding function for each node in a model. Normally you'll use the first way, but we'll show you both.

6.4.1 For arbitrary collections of nodes

```
model$y
## [1] 0.9101742 -5.0000000 1.7672873 0.7167075 0.3841854

simulate(model, 'y[1:3]')
model$y
```

```
## [1] 10.3195078 2.9896248 3.5401512 0.7167075 0.3841854

simulate(model, 'y')
model$y

## [1] 9.529274 3.393389 4.344205 3.757832 3.988094

model$z

##           [,1]      [,2]      [,3]
## [1,] 0.2670988 1.5868335 -0.47340064
## [2,] -0.5425200 0.5584864 -0.62036668
## [3,] 1.2078678 -1.2765922 0.04211587
## [4,] 1.1604026 -0.5732654 -0.91092165
## [5,] 0.7002136 -1.2246126 0.15802877

simulate(model, c('y[1:3]', 'z[1:5, 1:3]'))
model$y

## [1] 4.117366 6.562761 4.439232 3.757832 3.988094

model$z

##           [,1]      [,2]      [,3]
## [1,] 0.2670988 1.5868335 -0.47340064
## [2,] -0.5425200 0.5584864 -0.62036668
## [3,] 1.2078678 -1.2765922 0.04211587
## [4,] 1.1604026 -0.5732654 -0.91092165
## [5,] 0.7002136 -1.2246126 0.15802877

simulate(model, c('z[1:5, 1:3]'), includeData = TRUE)
model$z

##           [,1]      [,2]      [,3]
## [1,] 4.066770 4.251670 4.095908
## [2,] 6.544805 6.552742 6.634027
## [3,] 4.431875 4.435468 4.371066
## [4,] 3.725405 3.763848 3.698943
## [5,] 4.041243 3.836254 4.018749
```

Notice the following.

1. Inputs like 'y[1:3]' are automatically expanded into c('y[1]', 'y[2]', 'y[3]'). In fact, simply 'y' will be expanded into all nodes within y.
2. An arbitrary number of nodes can be provided as a character vector.
3. Simulations will be done in the order provided, so in practice the nodes should often

be obtained by functions like `getDependencies` described below. These return nodes in topologically sorted order, which means no node comes before something it depends on.

4. The data nodes `z` were not simulated into until `includeData = TRUE` was used.

Use of `calculate`, `calculateDiff` and `getLogProb` are similar to `simulate`, except that they return a value (described above) and they have no `includeData` argument.

6.4.2 Direct access to each node's functions

Access to the underlying `calculate`, `calculateDiff`, `simulate`, and `getLogProb` functions built by NIMBLE can be had as follows:

```
y2lp <- model$nodes[['y[2]']]$calculate()
y2lp

## [1] -2.192342

model$nodes[['y[2]']]$getLogProb()

## [1] -2.192342
```

6.5 Querying model structure

NIMBLE provides functions for asking a model about its structure. These can be used from R, including from the setup code of a `nimbleFunction` (setup code is described in Chapter 9).

Here we demonstrate this functionality using the *pump* example because it has a few more interesting components than the example above.

```
## defining model...
## building model...
## setting data and initial values...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)
## model building finished
```

6.5.1 getNodeNames, getVarNames, and expandNodeNames

First we'll see how to determine the nodes and variables in a model.

```
pump$getNodeNames()
```

```

## [1] "alpha"          "beta"
## [3] "lifted_d1_over_beta" "theta[1]"
## [5] "theta[2]"         "theta[3]"
## [7] "theta[4]"         "theta[5]"
## [9] "theta[6]"         "theta[7]"
## [11] "theta[8]"         "theta[9]"
## [13] "theta[10]"        "lambda[1]"
## [15] "lambda[2]"        "lambda[3]"
## [17] "lambda[4]"        "lambda[5]"
## [19] "lambda[6]"        "lambda[7]"
## [21] "lambda[8]"        "lambda[9]"
## [23] "lambda[10]"       "x[1]"
## [25] "x[2]"             "x[3]"
## [27] "x[4]"             "x[5]"
## [29] "x[6]"             "x[7]"
## [31] "x[8]"             "x[9]"
## [33] "x[10]"

pump$getNodeNames(determOnly = TRUE)

## [1] "lifted_d1_over_beta" "lambda[1]"
## [3] "lambda[2]"          "lambda[3]"
## [5] "lambda[4]"          "lambda[5]"
## [7] "lambda[6]"          "lambda[7]"
## [9] "lambda[8]"          "lambda[9]"
## [11] "lambda[10]"

pump$getNodeNames(stochOnly = TRUE)

## [1] "alpha"      "beta"      "theta[1]"  "theta[2]"  "theta[3]"
## [6] "theta[4]"  "theta[5]"  "theta[6]"  "theta[7]"  "theta[8]"
## [11] "theta[9]"  "theta[10]" "x[1]"      "x[2]"      "x[3]"
## [16] "x[4]"      "x[5]"      "x[6]"      "x[7]"      "x[8]"
## [21] "x[9]"      "x[10]"

pump$getNodeNames(dataOnly = TRUE)

## [1] "x[1]"  "x[2]"  "x[3]"  "x[4]"  "x[5]"  "x[6]"  "x[7]"
## [8] "x[8]"  "x[9]"  "x[10]"

pump$getVarNames()

## [1] "lifted_d1_over_beta" "theta"
## [3] "lambda"              "x"
## [5] "alpha"               "beta"

```

Note that some of the nodes may be “lifted” nodes introduced by NIMBLE (Section 5.2.9).

Next note that we can determine the set of nodes contained in one or more nodes or variables using `expandNodeNames`. The `returnScalarComponents` argument also allows us to return all of the scalar components of multivariate nodes. to illustrate.

```
multiVarCode2 <- nimbleCode({
  X[1, 1:5] ~ dnorm(mu[], cov[,])
  X[6:10, 3] ~ dnorm(mu[], cov[,])
  for(i in 1:4)
    Y[i] ~ dnorm(mn, 1)
})

multiVarModel2 <- nimbleModel(multiVarCode2, dimensions = list(mu = 5, cov = c(5,5)),
                             check = FALSE)

## defining model...
## building model...
## model building finished

multiVarModel2$expandNodeNames('Y')

## [1] "Y[1]" "Y[2]" "Y[3]" "Y[4]"

multiVarModel2$expandNodeNames(c('X', 'Y'), returnScalarComponents = TRUE)

## [1] "X[1, 1]" "X[1, 2]" "X[1, 3]" "X[6, 3]" "X[7, 3]"
## [6] "X[8, 3]" "X[9, 3]" "X[10, 3]" "X[1, 4]" "X[1, 5]"
## [11] "Y[1]" "Y[2]" "Y[3]" "Y[4]"
```

6.5.2 getDependencies

Next we’ll see how to determine the node dependencies (or “descendants”) in a model. There are a variety of arguments to `getDependencies` that allow one to specify whether to include the node itself, whether to include deterministic or stochastic or data dependents, etc. By default `getDependencies` returns descendants up to the next stochastic node on all edges emanating from the node(s) specified as input. This is what would be needed to calculate a Metropolis-Hastings acceptance probability in MCMC, for example.

```
pump$getDependencies('alpha')

## [1] "alpha" "theta[1]" "theta[2]" "theta[3]" "theta[4]"
## [6] "theta[5]" "theta[6]" "theta[7]" "theta[8]" "theta[9]"
## [11] "theta[10]"
```

```

pump$getDependencies(c('alpha', 'beta'))

## [1] "alpha"          "beta"
## [3] "lifted_d1_over_beta" "theta[1]"
## [5] "theta[2]"        "theta[3]"
## [7] "theta[4]"        "theta[5]"
## [9] "theta[6]"        "theta[7]"
## [11] "theta[8]"        "theta[9]"
## [13] "theta[10]"

pump$getDependencies('theta[1:3]', self = FALSE)

## [1] "lambda[1]" "lambda[2]" "lambda[3]" "x[1]"      "x[2]"
## [6] "x[3]"

pump$getDependencies('theta[1:3]', stochOnly = TRUE, self = FALSE)

## [1] "x[1]" "x[2]" "x[3]"

# get all dependencies, not just the direct descendants
pump$getDependencies('alpha', downstream = TRUE)

## [1] "alpha"          "theta[1]"      "theta[2]"      "theta[3]"
## [5] "theta[4]"      "theta[5]"      "theta[6]"      "theta[7]"
## [9] "theta[8]"      "theta[9]"      "theta[10]"     "lambda[1]"
## [13] "lambda[2]"     "lambda[3]"     "lambda[4]"     "lambda[5]"
## [17] "lambda[6]"     "lambda[7]"     "lambda[8]"     "lambda[9]"
## [21] "lambda[10]"    "x[1]"          "x[2]"          "x[3]"
## [25] "x[4]"          "x[5]"          "x[6]"          "x[7]"
## [29] "x[8]"          "x[9]"          "x[10]"

pump$getDependencies('alpha', downstream = TRUE, dataOnly = TRUE)

## [1] "x[1]" "x[2]" "x[3]" "x[4]" "x[5]" "x[6]" "x[7]"
## [8] "x[8]" "x[9]" "x[10]"

```

6.5.3 isData

Finally, you can query whether a node is flagged as data using the `isData` method applied to one or more nodes:

```

pump$isData('x[1]')

## [1] TRUE

```

```
pump$isData(c('x[1]', 'x[2]', 'alpha'))
## [1] TRUE TRUE FALSE
```

You can also query variables to determine if the nodes that are part of a variable are data nodes.

```
pump$isData('x')
## [1] TRUE TRUE TRUE TRUE TRUE TRUE TRUE TRUE TRUE TRUE

pump$isData('x[1:3]')
## [1] TRUE TRUE TRUE
```

6.6 The *modelValues* data structure

`modelValues` are containers designed for storing values for models. They may be used for model outputs or model inputs. A `modelValues` object will contain *rows* of variables. Each row contains one object of each variable, which may be multivariate. The simplest way to build a `modelValues` object is from a model object. This will create a `modelValues` object with the same variables as the model. Although they were motivated by models, one is free to set up a `modelValues` with any variables one wants.

```
pumpModelValues = modelValues(pumpModel, m = 2)
pumpModel$x
## [1] 5 1 5 14 3 19 1 1 4 22

pumpModelValues$x
## [[1]]
## [1] NA NA NA NA NA NA NA NA NA NA
##
## [[2]]
## [1] NA NA NA NA NA NA NA NA NA NA
```

In this example, `pumpModelValues` has the same variables as `pumpModel`, and we set `pumpModelValues` to have `m = 2` rows. As you can see, the rows are stored as elements of a list.

Alternatively, one can define a `modelValues` object manually via the `modelValuesSpec` function, like this:

```

mvSpec = modelValuesSpec(vars = c('a', 'b', 'c'),
                          type = c('double', 'int', 'double'),
                          size = list( a = 2, b =c(2,2) , c = 1) )

customMV = modelValues(mvSpec, m = 2 )
customMV$a

## [[1]]
## [1] NA NA
##
## [[2]]
## [1] NA NA

```

The arguments to `modelValuesSpec` are matching lists of variable names, types, and sizes. See `help(modelValuesSpec)` for more details. Note that in R execution, the types are not enforced. But they will be the types created in C++ code during compilation, so they should be specified carefully.

The object returned by `modelValues` is an uncompiled `modelValues`. When a `nimbleFunction` is compiled, any `modelValues` objects it uses are also compiled. A NIMBLE model always contains a `modelValues` that it uses as a default location to store its variables.

Here is an example where the `customMV` created above is used as the `setup` argument for a `nimbleFunction`, which is then compiled. Its compiled `mv` is then accessed with `$`.

```

# Simple nimbleFunction that uses a modelValues object
resizeFunction_Gen <- nimbleFunction(
  setup = function(mv){},
  run = function(k = integer() ){
    resize(mv,k)} )

rResize <- resizeFunction_Gen(customMV)
cResize <- compileNimble(rResize)
cCustomMV <- cResize$mv
# cCustomMV is a C++ modelValues object

```

Compiled `modelValues` objects can be accessed and altered in all the same ways as uncompiled ones. However, only uncompiled `modelValues` can be used as arguments to `setup` code in `nimbleFunctions`.

6.6.1 Accessing contents of `modelValues`

The values in a `modelValues` object can be accessed in several ways from R, and in fewer ways from NIMBLE.

```

# Sets the first row of a to (0, 1). R only.
customMV[['a']] [[1]] <- c(0,1)

# Sets the second row of a to (2, 3)
customMV['a', 2] <- c(2,3)

#Can access subsets of each row in standard R manner
customMV['a', 2][2] <- 4

# Accesses all values of 'a'. Output is a list. R only.
customMV[['a']]

## [[1]]
## [1] 0 1
##
## [[2]]
## [1] 2 4

# Sets the first row of b to a matrix with values 1. R only.
customMV[['b']] [[1]] <- matrix(1, nrow = 2, ncol = 2)

# Sets the second row of b. R only.
customMV[['b']] [[2]] <- matrix(2, nrow = 2, ncol = 2)

# Make sure the size of inputs is correct
# customMV['a', 1] <- 1:10
# Problem: dimension of 'a' is 2, not 10!
# Will cause problems when compiling nimbleFunction using customMV

```

Currently, only the syntax `customMV['a', 2]` works in the NIMBLE language, not `customMV[['a']] [[2]]`. Also note that `c()` does not work in NIMBLE, but one can do `customMV['a', 2] <- X[1:2]`.

We can query and change the number of rows using `getsize` and `resize`, respectively. These work in both R and NIMBLE. Note that we don't specify the variables in this case: all variables in a `modelValues` object will have the same number of rows.

```

getsize(customMV)

## [1] 2

resize(customMV, 3)
getsize(customMV)

## [1] 3

customMV$a

```

```
## [[1]]
## [1] 0 1
##
## [[2]]
## [1] 2 4
##
## [[3]]
## [1] NA NA
```

Often it is useful to convert a `modelValues` object to a matrix for use in R. For example, we may want to convert MCMC output into a matrix for use with the `coda` package for processing MCMC samples. This can be done with the `as.matrix` method for `modelValues` objects. This will generate column names from every scalar element of variables (e.g. `"x[1, 1]"`, `"x[2, 1]"`, etc.). The rows of the `modelValues` will be the rows of the matrix, with any matrices or arrays converted to a vector based on column-major ordering.

```
as.matrix(customMV, 'a') # convert 'a'

##      a[1] a[2]
## [1,]    0    1
## [2,]    2    4
## [3,]   NA   NA

as.matrix(customMV) # convert all variables

##      a[1] a[2] b[1, 1] b[2, 1] b[1, 2] b[2, 2] c[1]
## [1,]    0    1        1        1        1        1    NA
## [2,]    2    4        2        2        2        2    NA
## [3,]   NA   NA        NA        NA        NA        NA    NA
```

If a variable is a scalar, using `unlist` in R to extract all rows as a vector can be useful.

```
customMV['c', 1] <- 1
customMV['c', 2] <- 2
customMV['c', 3] <- 3
unlist(customMV['c', ])

## [1] 1 2 3
```

Once we have a `modelValues` object, we can see the structure of its contents via the `varNames` and `sizes` components of the object.

```
customMV$varNames

## [1] "a" "b" "c"
```

```

customMV$sizes
## $a
## [1] 2
##
## $b
## [1] 2 2
##
## $c
## [1] 1

```

As with most NIMBLE objects, `modelValues` are passed by reference, not by value. That means any modifications of `modelValues` objects in either R functions or `nimbleFunctions` will persist outside of the function. This allows for more efficient computation, as stored values are immediately shared among `nimbleFunctions`.

```

alter_a <- function(mv){
  mv['a',1][1] <- 1
}
customMV['a', 1]

## [1] 0 1

alter_a(customMV)
customMV['a',1]

## [1] 1 1

#Note that the first row was changed

```

However, when you retrieve a variable from a `modelValues` object, the result is a standard R list, which is subsequently passed by value, as usual in R.

6.7 NIMBLE passes objects by reference

NIMBLE relies heavily on R's reference class system. When models, `modelValues`, and `nimbleFunctions` with setup code are created, NIMBLE generates a new, customized reference class definition for each. As a result, objects of these types are passed by reference and hence modified in place by most NIMBLE operations. This is necessary to avoid a great deal of copying and returning and having to reassign large objects, both in processing model and `nimbleFunctions` and in running algorithms.

One cannot generally copy NIMBLE models or `nimbleFunctions` (specializations or generators) in a safe fashion, because of the references to other objects embedded within NIMBLE objects. However, the model member function `newModel` will create a new copy of the model

from the same model definition (Section 5.3.4). This new model can then be used with newly instantiated `nimbleFunctions`.

The reliable way to create new copies of `nimbleFunctions` is to re-run the R function called `nimbleFunction` and record the result in a new object. For example, say you have a `nimbleFunction` called `foo` and 1000 instances of `foo` are compiled as part of an algorithm related to a model called `model1`. If you then need to use `foo` in an algorithm for another model, `model2`, doing so may work without any problems. However, there are cases where the NIMBLE compiler will tell you during compilation that the second set of `foo` instances cannot be built from the previous compiled version. A solution is to re-define `foo` from the beginning – i.e. call `nimbleFunction` again – and then proceed with building and compiling the algorithm for `model2`.

Chapter 7

MCMC

Using the MCMC engine provided with NIMBLE consists of several steps:

- Building an MCMC function specialized to a particular model. This can be done in one step, but when a user wants to customize the MCMC, it can be done in several steps:
 - Creating an MCMC configuration consisting of a set of sampler choices;
 - Customizing the sampler choices in the configuration, which may include providing new samplers written as `nimbleFunctions`; and
 - Building the MCMC function from the configuration.
- Compiling and running the MCMC function.
- Extracting the posterior samples.

This chapter also discusses:

- Sampling algorithms provided with NIMBLE.
- Default sampler assignments in an MCMC configuration.
- Writing new samplers that conform to NIMBLE’s MCMC system.
- Using `MCMCsuite` to automatically run WinBUGS, JAGS, Stan and/or multiple NIMBLE MCMCs on the same model.¹
- Using NIMBLE’s algorithm to search blocks of nodes for efficient joint (block) sampling.

7.1 The MCMC configuration

The MCMC configuration contains information needed for building an MCMC. We will show how to create this information as a first step so it can be customized before moving ahead, but when no customization is needed one can jump directly to the `buildMCMC` step below. An MCMC configuration includes:

- The model on which the MCMC will operate
- The model nodes which will be sampled (updated) during execution of the MCMC

¹We haven’t added OpenBUGS support yet.

- The particular sampling algorithms for each of these nodes, including any control parameters required by each sampling algorithm
- Two sets of variables that will be monitored (recorded) during execution of the MCMC and thinning intervals for how often each set will be recorded. Two sets are allowed because it can be useful to monitor different variables at different intervals.

7.1.1 Default MCMC configuration

Assuming we have a model named `Rmodel`, the following will generate a default MCMC configuration:

```
mcmcspec <- configureMCMC(Rmodel)
```

The default configuration will contain a single sampler for each node in the model, and the default ordering follows the topological ordering of the model. `configureMCMC` creates an *MCMCspec* reference class object. The *MCMCspec* reference class has a number of methods, such as `addSampler` that are described later.

Default assignment of sampler algorithms

The default sampling algorithm assigned to each stochastic node is determined by the following, in order of precedence:

1. If the node has no stochastic dependents, a predictive *end* sampler is assigned. The *end* sampling algorithm merely calls `simulate` on the particular node.
2. The node is checked for presence of a conjugate relationship between its prior distribution and the distributions of its stochastic dependents. If it is determined to be in a conjugate relationship, then the corresponding *conjugate* (Gibbs) sampler is assigned.
3. If the node is discrete-valued, then a *slice* sampler is assigned [4].
4. If the node follows a multivariate distribution, then a *RW_block* sampler is assigned for all elements. This is a Metropolis-Hastings adaptive random-walk sampler with a multivariate normal proposal [5].
5. If none of the above criteria are satisfied, then a *RW* sampler is assigned. This is a Metropolis-Hastings adaptive random-walk sampler with a univariate normal proposal distribution.

The control parameters governing each of the default sampling algorithms are defined in the NIMBLE system option `MCMCcontrolDefaultList`. These default values are described in Section 7.5, along with the related sampling algorithms.

Modifying the default sampler assignments

`configureMCMC` accepts control arguments `useConjugacy`, `onlyRW`, `onlySlice`, and `multivariateNodesAsScalars` to modify default sampler assignments.

See `help(configureMCMC)` for usage details.

Default monitors

The default MCMC configuration includes monitors on all top-level stochastic nodes of the model.

Automated parameter blocking

The default configuration may be replaced by that generated from an automated parameter blocking algorithm. This algorithm determines groupings of model nodes that, when jointly sampled with a `RW_block` sampler, increase overall MCMC efficiency. Overall efficiency is defined as the effective sample size of the slowest-mixing node divided by computation time. This is done by:

```
autoBlockSpec <- configureMCMC(Rmodel, autoBlock = TRUE)
```

In this usage, the additional control argument `autoIt` may also be provided to indicate the number of MCMC samples to be used in the automated blocking procedure (default 20,000). Note that this function compiles and runs MCMCs, progressively exploring different sampler assignments, so it takes some time and generates some output.

7.1.2 Customizing the MCMC configuration

The MCMC configuration may be customized in a variety of ways, either through additional named arguments to `configureMCMC` or by calling member methods of an existing `MCMCspec` object.

Default samplers for particular nodes

One can create an MCMC configuration with default samplers on just a particular set of nodes using the `nodes` argument to `configureMCMC`. The value for the `nodes` argument may be a character vector containing node and/or variable names. In the case of a variable name, a default sampler will be added for all stochastic nodes in the variable.

If the `nodes` argument is provided, default samplers are created only for the *stochastic* nodes specified by this argument (possibly including data nodes), and the ordering of these sampling algorithms matches the ordering within the `nodes` argument. It is worthwhile to note this is the *only* way in which a sampler may be placed on a data node, which upon execution of the MCMC will overwrite any value stored in the data node.

Creating a configuration with no samplers

If you plan to customize the choice of all samplers, it can be useful to obtain a configuration with no sampler assignments at all. This can be done by providing the `nodes` argument with the value `NULL`, `character()`, or `list()`.

Overriding the default sampler control list values

The default values of control list elements for all sampling algorithms may be overridden through use of the `control` argument to `configureMCMC`, which should be a named list. Named elements in the `control` argument will be used for all default samplers added. In addition, they are retained in the `MCMCspec` object, and will be used as defaults for any subsequent samplers added to this same `MCMCspec` object. For example, the following will create the default MCMC configuration, except all RW samplers will have their initial `scale` set to 3, and none of the samplers (*RW*, or otherwise) will be adaptive.

```
mcmcspec <- configureMCMC(Rmodel, control = list(scale = 3, adaptive = FALSE))
```

Note that when adding individual samplers (next), the default control list can be overridden.

Adding samplers to the configuration

Samplers may be added to a configuration using the `addSampler` method of the `MCMCspec` object. The first argument gives the node(s) to be sampled, called the `target`, as a character vector. The second argument gives the types of sampler, which may be provided as a character string or a `nimbleFunction` object. Valid character strings include ‘end’, ‘RW’, ‘RW_block’, ‘slice’, ‘crossLevel’, and ‘RW_llFunction’, which are described below. Requirements for writing a `nimbleFunction` that can be used as a sampler are also described below, and new samplers can be labeled with a `name` argument, which is used in output of `getSamplers`.

When a `control` argument is provided in a call to `addSampler`, the `control` list elements specified will have the highest priority. The hierarchy of precedence for control list elements for samplers is:

1. Those supplied in the `control` list argument to `addSampler`
2. Those supplied in the `control` list argument in the preceding call to `configureMCMC`
3. Those supplied in the NIMBLE system option `MCMCcontrolDefaultList`

A call to `addSampler` results in a single instance of the specified sampler, which will be specialized to the specified `target` model node or nodes, being added at end of the current sampler ordering.

Printing, re-ordering, and removing samplers

The current, ordered, list of all samplers in the MCMC configuration may be printed by calling the `getSamplers` method. When you want to see only samplers acting on specific model nodes or variables, provide those names as an argument to `getSamplers`.

The existing samplers may be re-ordered using the `setSamplers` method. The `ind` argument is a vector of sampler indices, or a character vector of model node or variable names. The samplers in the MCMC configuration will be replaced by the samplers corresponding to the indices provided, or those samplers acting on the target nodes specified. Here are a few

examples. Each example assumes the `MCMCspec` object initially contains 10 samplers, and each example is independent of the others.

```
## Truncate the current list of samplers to the first 5
mcmcspec$setSamplers(ind = 1:5)

## Retain only the third sampler, which will subsequently
## become the first sampler
mcmcspec$setSamplers(ind = 3)

## Reverse the ordering of the samplers
mcmcspec$setSamplers(ind = 10:1)

## The new set of samplers becomes the
## {first, first, first, second, third} from the current list.
## Upon each iteration of the MCMC, the 'first' sampler will
## be executed 3 times, however each instance of the sampler
## will be independent in terms of scale, adaptation, etc.
mcmcspec$setSamplers(ind = c(1, 1, 1, 2, 3))

## Set the list of samplers to only those acting on model node 'alpha'
mcmcspec$setSamplers('alpha')

## Set the list of samplers to those acting on any components of the
## model variables 'x', 'y', or 'z'.
mcmcspec$setSamplers(c('x', 'y', 'z'))
```

Samplers may be removed from the current sampler ordering with the `removeSamplers` method. The following examples demonstrate this usage, where again each example assumes that `mcmcspec` initially contains 10 samplers, and each example is independent of the others. `removeSamplers` may also accept a character vector argument, and will remove all samplers acting on these target model nodes.

```
## Remove the first sampler
mcmcspec$removeSamplers(ind = 1)

## Remove the last five samplers
mcmcspec$removeSamplers(ind = 6:10)

## Remove all samplers,
## resulting in an empty MCMC configuration, containing no samplers
mcmcspec$removeSamplers(ind = 1:10)

## Remove all samplers acting on 'x' or any component of it
mcmcspec$removeSamplers('x')
```

```
## Default: providing no argument removes all samplers
mcmcspec$removeSamplers()
```

Monitors and thinning intervals

An `MCMCspec` object contains two independent lists of variables to monitor, which correspond to two independent thinning intervals: `thin` corresponding to `monitors`, and `thin2` corresponding to `monitors2`. Monitors operate at the *variable* level. Only entire model variables may be monitored. Specifying a monitor on a *node*, e.g., `x[1]`, will result in the entire variable `x` being monitored.

The variables specified in `monitors` and `monitors2` will be recorded (with thinning interval `thin`) into the `mvSamples` and `mvSamples2` – both *modelValues* objects – of the MCMC, respectively. See Section 7.4 for information about extracting these *modelValues* objects from the MCMC algorithm object.

Monitors may be added to the MCMC configuration either in the original call to `configureMCMC` or using the `addMonitors` method:

```
## Using an arguments to configureMCMC
mcmcspec <- configureMCMC(Rmodel, monitors = c('alpha', 'beta'), monitors2 = 'x')

## Calling a member method of the mcmcspec object
## This results in the same monitors as above
mcmcspec$addMonitors(c('alpha', 'beta'))
mcmcspec$addMonitors2('x')
```

Similarly, either thinning interval may be set at either step:

```
## Using an argument to configureMCMC
mcmcspec <- configureMCMC(Rmodel, thin = 1, thin2 = 100)

## Calling a member method of the mcmcspec object
## This results in the same thinning intervals as above
mcmcspec$setThin(1)
mcmcspec$setThin2(100)
```

The current lists of monitors, and thinning intervals, may be displayed using the `getMonitors` method. Both sets of monitors (`monitors` and `monitors2`) may be reset to empty character vectors by calling the `resetMonitors` method.

7.2 Building and compiling the MCMC algorithm

Once the MCMC configuration object has been created, and customized to one's liking, it may be used to build an MCMC function:

```
Rmcmc <- buildMCMC(mcmcspec)
```

`buildMCMC` is a `nimbleFunction`. The returned object `Rmcmc` is an instance of the NIMBLE function specific to configuration `mcmcspec`.

When no customization is needed, one can skip `configureMCMC` and simply provide a model object to `buildMCMC`. The following two MCMC functions will be identical:

```
mcmcspec <- configureMCMC(Rmodel)  ## default MCMC configuration
Rmcmc1 <- buildMCMC(mcmcspec)

Rmcmc2 <- buildMCMC(Rmodel)  ## uses the default configuration for Rmodel
```

For speed of execution, we usually desire to compile the MCMC function to C++ (as is the case for other NIMBLE functions). To do so, we use `compileNimble`. Care must be taken to perform this compilation in the same project that contains the underlying model and compiled model objects. A typical compilation call looks like:

```
Cmcmc <- compileNimble(Rmcmc, project = Rmodel)
```

Alternatively, if the model has not already been compiled, they can be compiled together in one line:

```
Cmcmc <- compileNimble(Rmodel, Rmcmc)
```

7.3 Executing the MCMC algorithm

The MCMC function (either the compiled or uncompiled version) has one required argument, `niter`, representing the number of iterations to run the MCMC algorithm. We'll assume the function is called `mcmc`. Calling `mcmc(niter)` causes the full list of samplers (as determined from the input `MCMCspec` object) to be executed `niter` times, and the monitored variables to be stored into the internal `mvSamples` and/or `mvSamples2` objects as governed by the corresponding thinning intervals.

The `mcmc` function has an optional `reset` argument. When `reset = TRUE` (the default value), the following occurs at the onset of the call to `mcmc$run()`:

- All model nodes are checked that they contain values, and that model log-probabilities are up-to-date with the current node values. If a stochastic node is missing a value, it is populated using a call to `simulate`. The values of deterministic nodes are calculated, to be consistent with their parent nodes. If any right-hand-side-only nodes are missing a value, an error results.
- All MCMC sampler functions are reset to their initial state: the initial values of any sampler control parameters (e.g., `scale`, `sliceWidth`, or `propCov`) are reset to their initial values, as were specified by the original MCMC configuration.

- The internal *modelValues* objects `mvSamples` and `mvSamples2` are each resized to the appropriate length for holding the requested number of samples (`niter/thin`, and `niter/thin2`, respectively).

When `mcmc$run(niter, reset = FALSE)` is called, the MCMC algorithm picks up from where it left off. No values in the model are checked or altered, and sampler functions are not reset to their initial states. Further, the internal *modelValues* objects containing samples are each increased in size to appropriately accommodate the additional samples.

Further arguments and details can be found by `help(buildMCMC)`.

7.4 Extracting MCMC samples

After executing the MCMC, the output samples can be extracted as follows as:

```
mvSamples <- mcmc$mvSamples
mvSamples2 <- mcmc$mvSamples2
```

These *modelValues* objects can be converted into matrices using `as.matrix`:

```
samplesMatrix <- as.matrix(mvSamples)
samplesMatrix2 <- as.matrix(mvSamples2)
```

The column names of the matrices will be the node names of nodes in the monitored variables. Then, for example, the mean of the samples for node `x[2]` could be calculated as:

```
mean(samplesMatrix[, 'x[2]'])
```

7.5 Sampler Algorithms provided with NIMBLE

We now describe the samplers provided with NIMBLE. The MCMC configuration for a model generated from the following model code will serve as our example for this section:

```
code <- nimbleCode({
  a ~ dgamma(1, 1)
  b ~ dgamma(1, 1)
  p ~ dbeta(a, b)
  y1 ~ dbinom(prob = p, size = 10)
  y2 ~ dbinom(prob = p, size = 20)
})
```

7.5.1 Terminal node end sampler

The `end` sampler is only appropriate for use on terminal stochastic nodes (that is, those having no stochastic dependencies). Note that such nodes play no role in inference but have often been included in BUGS models to accomplish posterior predictive checks. NIMBLE allows posterior predictive values to be simulated independently of running MCMC, for example by writing a `nimbleFunction` to do so. This means that in many cases where terminal stochastic nodes have been included in BUGS models, they are not needed when using NIMBLE.

The `end` sampler functions by calling the `simulate` method of the relevant node, then updating model probabilities and deterministic dependent nodes. The `end` sampler will automatically be assigned to all terminal, non-data stochastic nodes in a model by the default MCMC configuration, so it is uncommon to manually assign this sampler. The `end` sampler accepts no control list arguments.

Example usage:

```
mcmcspec$addSampler(target = 'y[1]', type = 'end')
```

7.5.2 Scalar Metropolis-Hastings random walk RW sampler

The RW sampler executes adaptive Metropolis-Hastings sampling with a normal proposal distribution, implementing the adaptation routine given in [6]. This sampler can be applied to any scalar continuous-valued stochastic node.

The RW sampler can be customized using the `control` list argument to set the initial proposal distribution scale, and the adaptive properties of the sampler. See `help(samplers)` for details.

Example usage:

```
mcmcspec$addSampler(target = 'a', type = 'RW',
  control = list(adaptive = FALSE, scale = 3))

mcmcspec$addSampler(target = 'b', type = 'RW',
  control = list(adaptive = TRUE, adaptInterval = 200))
```

Note that because we use a simple normal proposal distribution on all nodes, negative proposals may be simulated for non-negative random variables. These will be rejected, so the only downsides to this are some inefficiency and the presence of warnings during uncompiled (but not compiled) execution indicating NA or NaN values.

7.5.3 Multivariate Metropolis-Hastings RW_block sampler

The `RW_block` sampler performs a simultaneous update of one or more model nodes, using an adaptive Metropolis-Hastings algorithm with a multivariate normal proposal distribution [5], implementing the adaptation routine given in [6]. This sampler may be applied to any

set of continuous-valued model nodes, to any single continuous-valued multivariate model node, or to any combination thereof.

The `RW_block` sampler can be customized using the `control` list argument to set the initial proposal covariance, and the adaptive properties of the sampler. See `help(samplers)` for details.

Example usage:

```
mcmcspec$addSampler(target = c('a', 'b', 'c'), type = 'RW_block')
```

7.5.4 slice sampler

The `slice` sampler performs slice sampling of the scalar node to which it is applied [4]. This sampler can operate on either continuous-valued or discrete-valued scalar nodes. The slice sampler performs a “stepping out” procedure, in which the slice is iteratively expanded to the left or right by an amount `sliceWidth`. This sampler is optionally adaptive, whereby the value of `sliceWidth` is adapted towards the observed absolute difference between successive samples.

The `slice` sampler can be customized using the `control` list argument to set the initial slice width, and the adaptive properties of the sampler. See `help(samplers)` for details.

Example usage:

```
mcmcspec$addSampler(target = 'y[1]', type = 'slice',
  control = list(adaptive = FALSE, sliceWidth = 3))

mcmcspec$addSampler(target = 'y[2]', type = 'slice',
  control = list(adaptive = TRUE, sliceMaxSteps = 1))
```

7.5.5 Hierarchical crossLevel sampler

This sampler is constructed to perform simultaneous updates across two levels of stochastic dependence in the model structure. This is possible when all stochastic descendents of node(s) at one level have conjugate relationships with their own stochastic descendents. In this situation, a Metropolis-Hastings algorithm may be used, in which a multivariate normal proposal distribution is used for the higher-level nodes, and the corresponding proposals for the lower-level nodes undergo Gibbs (conjugate) sampling. The joint proposal is either accepted or rejected for all nodes involved based upon the Metropolis-Hastings ratio.

The `crossLevel` sampler can be customized using the `control` list argument to set the initial proposal covariance and the adaptive properties for the Metropolis-Hastings sampling of the higher-level nodes. See `help(samplers)` for details.

Example usage:

```
mcmcSpec$addSampler(target = c('a', 'b', 'c'), type = 'crossLevel')
```

The requirement that all stochastic descendants of the `target` nodes must themselves have only conjugate descendants will be checked when the MCMC algorithm is built. This sampler is useful when there is strong dependence across the levels of a model that causes problems with convergence or mixing.

7.5.6 Customized log likelihood evaluations using the `RW_llFunction` sampler

Sometimes it is useful to control the log likelihood calculations used for an MCMC updater instead of simply using the model. For example, one could use a sampler with a log likelihood that analytically (or numerically) integrates over latent model nodes. Or one could use a sampler with a log likelihood that comes from a stochastic approximation such as a particle filter (see below), allowing composition of a particle MCMC (PMCMC) algorithm [1]. The `RW_llFunction` sampler handles this by using a Metropolis-Hastings algorithm with a normal proposal distribution and a user-provided log-likelihood function. To allow compiled execution, the log-likelihood function must be provided as a specialized instance of a `nimbleFunction`. The log-likelihood function may use the same model as the MCMC as a setup argument (as does the example below), but if so the state of the model should be unchanged during execution of the function (or you must understand the implications otherwise).

The `RW_llFunction` sampler can be customized using the `control` list argument to set the initial proposal distribution scale and the adaptive properties for the Metropolis-Hastings sampling. In addition, the `control` list argument must contain a named `llFunction` element, which is specialized `nimbleFunction` that accepts no arguments and returns a scalar double number. The return value must be the total log-likelihood of all stochastic dependents of the `target` nodes – and, if `includesTarget = TRUE`, of the target node(s) themselves – or whatever surrogate is being used for the total log-likelihood. This is a required `control` list element with no default. See `help(samplers)` for details.

Complete example of correct usage:

```
code <- nimbleCode({
  p ~ dunif(0, 1)
  y ~ dbin(p, n)
})

Rmodel <- nimbleModel(code, data = list(y=3), inits = list(p=0.5, n=10))

llFun <- nimbleFunction(
  setup = function(model) { },
  run = function() {
    y <- model$y
    p <- model$p
  }
)
```

```

    n <- model$n
    ll <- lfactorial(n) - lfactorial(y) - lfactorial(n-y) +
        y * log(p) + (n-y) * log(1-p)
    returnType(double())
    return(ll)
  }
)

RllFun <- llFun(Rmodel)

mcmcspec <- configureMCMC(Rmodel, nodes = NULL)

mcmcspec$addSampler(target = 'p', type = 'RW_llFunction',
  control = list(llFunction = RllFun, includesTarget = FALSE))

Rmcmc <- buildMCMC(mcmcspec)

```

7.5.7 Conjugate (Gibbs) samplers

Gibbs samplers can be provided for nodes in conjugate relationships, as specified by the system-level `conjugacyRelationshipsInputList`. Conjugate samplers should not, in general, be manually added or modified by a user, since the control list requisites and syntax are lengthy, and determining conjugacy and assigning conjugate samplers is fully handled by the default MCMC configuration.

A model may be checked for conjugate relationships using `model$checkConjugacy`. This returns a named list describing all conjugate nodes. `checkConjugacy` can also accept a character vector argument specifying a subset of model node names to check for conjugacy.

The current release of NIMBLE supports conjugate sampling of the relationships listed in Table 7.1.

Conjugate sampler functions may (optionally) dynamically check that their own posterior likelihood calculations are correct. If incorrect, a warning is issued. However, this functionality will roughly double the run-time required for conjugate sampling. By default, this option is disabled in NIMBLE. This option may be enabled by executing the following:

```

nimbleOptions(verifyConjugatePosteriors = TRUE)

buildConjugateSamplerFunctions()

```

7.6 Detailed MCMC example: litters

Here is a detailed example of specifying, building, compiling, and running two MCMC algorithms. We use the `litters` example from the BUGS examples.

Prior Distribution	Sampling Distribution	Parameter
Beta	Bernoulli	prob
	Binomial	prob
	Negative Binomial	prob
Dirichlet	Multinomial	prob
Gamma	Poisson	lambda
	Normal	tau
	Lognormal	taulog
	Gamma	rate
	Exponential	rate
Normal	Normal	mean
	Lognormal	meanlog
Multivariate Normal	Multivariate Normal	mean
Wishart	Multivariate Normal	prec

Table 7.1: Conjugate relationships supported by NIMBLE's MCMC engine.

7.7 Comparing different MCMC engines with MCMCsuite

NIMBLE's `MCMCsuite` function automatically runs WinBUGS, JAGS, Stan, and/or multiple NIMBLE configurations on the same model. Note that the BUGS code must be compatible with whichever BUGS packages are included, and separate Stan code must be provided.

We show how to use `MCMCsuite` for the same `litters` example used in 7.6. Subsequently, additional details of the `MCMCsuite` are given.

7.7.1 MCMC Suite example: litters

The following code executes the following MCMC algorithms on the `litters` example:

1. WinBUGS
2. JAGS
3. NIMBLE default configuration
4. NIMBLE configuration with argument `onlySlice = TRUE`
5. NIMBLE custom configuration using two `crossLevel` samplers

```
output <- MCMCsuite(
  code = litters_code,
  constants = constants,
  data = data,
  inits = inits,
  monitors = 'mu',
  MCMCs = c('bugs', 'jags', 'nimble', 'nimble_slice', 'nimble_CL'),
  MCMCdefs = list(
    nimble_CL = quote({
      mcmcspec <- configureMCMC(Rmodel, nodes = NULL)
      mcmcspec$addSampler(target = c('a[1]', 'b[1]'), type = 'crossLevel')
      mcmcspec$addSampler(target = c('a[2]', 'b[2]'), type = 'crossLevel')
      mcmcspec
    })),
  plotName = 'littersSuite'
)
```

7.7.2 MCMC Suite outputs

Executing the MCMC Suite returns a named list containing three elements, as well as generates and saves traceplots and posterior density plots. The elements of this return list object are:

Samples

`samples` is a three-dimensional array, containing all MCMC samples from each algorithm. The first dimension of the `samples` array corresponds to each MCMC algorithm, and may

be indexed by the name of the algorithm. The second dimension of the `samples` array corresponds to each node which was monitored, and may be indexed by the node name. The third dimension of `samples` contains the MCMC samples, and has length `niter/thin - burnin`.

Summary

The MCMC suite output contains a variety of pre-computed summary statistics, which are stored in the `summary` matrix. For each monitored node and each MCMC algorithm, the following default summary statistics are calculated: `mean`, `median`, `sd`, the 2.5% quantile, and the 97.5% quantile. These summary statistics are easily viewable, as:

```
output$summary
# , , mu[1]
#           mean      median      sd  quant025  quant975

Timing

`timing` contains a named vector of the runtime for each MCMC algorithm, the total compile time for the NIMBLE model and MCMC algorithms, and the compile time for Stan (if specified). All run- and compile- times are given in minutes.

Plots

Executing the MCMC Suite provides and saves several plots. These include trace plots and posterior density plots for each monitored node, under each algorithm.

Note that the generation of MCMC Suite plots *in Rstudio* may result in several warning messages from R (regarding graphics devices), but will function without any problems.

7.7.3 Customizing MCMC Suite

An MCMC Suite is customizable in terms of all of the following:

- MCMC algorithms to execute, optionally including WinBUGS, JAGS, Stan, and various flavours of NIMBLE's MCMC
- Custom-specified NIMBLE MCMC algorithms
- Automated parameter blocking for efficient MCMC sampling
- Nodes to monitor
- Number of MCMC iterations
- Thinning interval
- Burn-in
- Summary statistics to report
- Generating and saving plots

NIMBLE MCMC algorithms may be specified using the `MCMCs` argument to `MCMCsuite`, which is character vector defining the MCMC algorithms to run. The `MCMCs` argument may include any of the following algorithms:

```

'bugs' WinBUGS MCMC algorithm
'jags' JAGS MCMC algorithm
'Stan' Stan MCMC algorithm
'nimble' NIMBLE MCMC using the default configuration
'nimble_RW' NIMBLE MCMC using the default configuration with onlyRW = TRUE
'nimble_slice' NIMBLE MCMC using the default configuration with onlySlice= TRUE
'autoBlock' NIMBLE MCMC algorithm with block sampling of dynamically determined
parameter groups attempting to maximize sampling efficiency

```

The default value for the `MCMCs` argument is `c('jags', 'nimble', 'nimble_RW', 'nimble_slice', 'autoBlock')`.

The names of additional, custom, MCMC algorithms may also be provided in the `MCMCs` argument, so long as these custom algorithms are defined in the `MCMCdefs` argument. An example of this usage is given with the `crossLevel` algorithm in the `litters` MCMC Suite example.

The `MCMCdefs` may be provided as named list of definitions, for any custom MCMC algorithms specified in the `MCMCs` argument. If `MCMCs` specified an algorithm called `'myMCMC'`, then `MCMCdefs` must contain an element named `'myMCMC'`. The contents of this element must be a block of code that, when executed, returns the desired MCMC configuration object. This block of code may assume the existence of the R model object, `Rmodel`. Further, this block of code need not worry about adding monitors to the MCMC configuration; it need only specify the samplers.

As a final important point, execution of this block of code must *return* the MCMC configuration object. Therefore, elements supplied in the `MCMCdefs` argument should usually take the form:

```
MCMCdefs = list(
  myMCMC = quote({
    mcmcspec <- configureMCMC(Rmodel, ....)
    mcmcspec$addSampler(.....)
    mcmcspec      ## returns the MCMC configuration object
  })
)
```

Full details of the arguments and customization of the MCMC Suite is available through the R help using `help(MCMCsuite)`.

7.8 Advanced topics

7.8.1 Custom sampler functions

The following code illustrates how a NIMBLE developer would implement and use a Metropolis-Hastings random walk sampler with fixed proposal standard deviation. The comments accompanying the code explain the necessary characteristics of all sampler functions.

```
## the name of this sampler function, for the purposes of
## adding it to MCMC configurations, will be 'my_RW'
my_RW <- nimbleFunction(

  ## sampler functions must contain 'sampler_BASE'
  contains = sampler_BASE,

  ## sampler functions must have exactly these setup arguments:
  ## model, mvSaved, target, control
  setup = function(model, mvSaved, target, control) {
    ## first, extract the control list elements, which will
    ## dictate the behavior of this sampler.
    ## the setup code will be later processed to determine
    ## all named elements extracted from the control list.
    ## these will become the required elements for any
    ## control list argument to this sampler, unless they also
    ## exist in the NIMBLE system option 'MCMCcontrolDefaultList'.

    ## the random walk proposal standard deviation
    scale <- control$scale

    ## determine the list of all dependent nodes,
    ## up to the first layer of stochastic nodes, generally
    ## called 'calcNodes'. The values, inputs, and logProbs
    ## of these nodes will be retrieved and/or altered
```

```

    ## by this algorithm.
    calcNodes <- model$getDependencies(target)
  },

  ## the run function must accept no arguments, execute
  ## the sampling algorithm, leave the modelValues object
  ## 'mvSaved' as an exact copy of the updated values in model,
  ## and have no return value.  initially, mvSaved contains
  ## an exact copy of the values and logProbs in the model.
  run = function() {

    ## extract the initial model logProb
    model_lp_initial <- getLogProb(model, calcNodes)

    ## generate a proposal value for target node
    proposal <- rnorm(1, model[[target]], scale)

    ## store this proposed value into the target node.
    ## notice the double assignment operator, `<<-`,
    ## necessary because 'model' is a persistent member
    ## data object of this sampler.
    model[[target]] <<- proposal

    ## calculate target_logProb, propagate the
    ## proposed value through any deterministic dependents,
    ## and calculate the logProb for any stochastic
    ## dependnets.  The total (sum) logProb is returned.
    model_lp_proposed <- calculate(model, calcNodes)

    ## calculate the log Metropolis-Hastings ratio
    log_MH_ratio <- model_lp_proposed - model_lp_initial

    ## Metropolis-Hastings step: determine whether or
    ## not to accept the newly proposed value
    u <- runif(1, 0, 1)
    if(u < exp(log_MH_ratio)) jump <- TRUE
    else jump <- FALSE

    ## if we accepted the proposal, then store the updated
    ## values and logProbs from 'model' into 'mvSaved'.
    ## if the proposal was not accepted, restore the values
    ## and logProbs from 'mvSaved' back into 'model'.
    if(jump) copy(from = model, to = mvSaved, row = 1,
                 nodes = calcNodes, logProb = TRUE)
  }
}

```

```
    else      copy(from = mvSaved, to = model, row = 1,
                  nodes = calcNodes, logProb = TRUE)
  },

  ## sampler functions must have a member method 'reset',
  ## which takes no arguments and has no return value.
  ## this function is used to reset the sampler to its
  ## initial state. since this sampler function maintains
  ## no internal member data variables, reset() needn't
  ## do anything.
  methods = list(
    reset = function () {}
  )
)

## now, assume the existence of an R model object 'Rmodel',
## which has a scalar-valued stochastic node 'x'

## create an MCMC configuration with no sampler functions
mcmcspec <- configureMCMC(Rmodel, nodes = NULL)

## add our custom-built random walk sampler on node 'x',
## with a fixed proposal standard deviation = 0.1
mcmcspec$addSampler(target = 'x', type = 'my_RW',
  control = list(scale = 0.1))

Rmcmc <- buildMCMC(mcmcspec)  ## etc...
```

Chapter 8

Other algorithms provided by NIMBLE

In v0.4, the NIMBLE algorithm library is fairly limited beyond MCMC. It includes some basic utilities for calculating and simulating sets of nodes. And it includes a couple of algorithms, particle filters and MCEM, that illustrate the kind of programming with models that can be done with NIMBLE.

8.1 Basic Utilities

8.1.1 `simNodes`, `calcNodes`, and `getLogProbs`

`simNodes`, `calcNodes` and `getLogProb` are basic nimbleFunctions that simulate, calculate, or get the log probabilities (densities), respectively, of the same set of nodes each time they are called. Each of these takes a model and a character string of node names as inputs. If `nodes` is left blank, then all the nodes of the model are used.

For `simNodes`, the nodes provided will be topologically sorted to simulate in the correct order. For `calcNodes` and `getLogProb`, the nodes will be sorted and dependent nodes will be included. Recall that the calculations must be up to date (from a `calculate` call) for `getLogProb` to return the values you are probably looking for.

```
simpleModelCode <- nimbleCode({
  for(i in 1:4){
    x[i] ~ dnorm(0,1)
    y[i] ~ dnorm(x[i], 1) #y depends on x
    z[i] ~ dnorm(y[i], 1) #z depends on y
    #z conditionally independent of x
  }
})

simpleModel <- nimbleModel(simpleModelCode)
```

```

## defining model...
## building model...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)

## NAs were detected in model variables: x, logProb_x, y, logProb_y, z, logProb_z.

## model building finished

cSimpleModel <- compileNimble(simpleModel)

#simulates all the x's and y's
rSimXY <- simNodes(simpleModel, nodes = c('x', 'y') )

#calls calculate on x and its dependents (y, but not z)
rCalcXDep <- calcNodes(simpleModel, nodes = 'x')

#calls getLogProb on x's and y's
rGetLogProbXDep <- getLogProbNodes(simpleModel,
                                   nodes = 'x')

#compiling the functions
cSimXY <- compileNimble(rSimXY, project = simpleModel)
cCalcXDep <- compileNimble(rCalcXDep, project = simpleModel)
cGetLogProbXDep <- compileNimble(rGetLogProbXDep,
                                 project = simpleModel)

cSimpleModel$x

## [1] NA NA NA NA

cSimpleModel$y

## [1] NA NA NA NA

#simulating x and y
cSimXY$run()

## NULL

cSimpleModel$x

## [1] 0.81408104 1.50846186 0.60719211 -0.03049741

cSimXY$run()

## NULL

#Gives old answer because logProbs
#not updated after 'simulate'
cGetLogProbXDep$run()

## [1] -10.34766

cCalcXDep$run()

## [1] -10.76837

```

8.1.2 simNodesMV, calcNodesMV, and getLogProbsMV

There is a similar trio of nimbleFunctions that does each job repeatedly for different rows of a modelValues object. For example, `simNodesMV` will simulate in the model multiple times and record each simulation in a row of its modelValues. `calcNodesMV` and `getLogProbsMV` iterate over the rows of a modelValues, copy the nodes into the model, and then do their job of calculating or collecting log probabilities (densities), respectively. Each of these returns a numeric vector with the summed log probabilities of the chosen nodes from each each row. `calcNodesMV` will save the log probabilities back into the modelValues object if `saveLP == TRUE`, a run-time argument.

Here are some examples:

```

mv <- modelValues(simpleModel)
rSimManyXY <- simNodesMV(simpleModel, nodes = c('x', 'y'), mv = mv)
rCalcManyXDeps <- calcNodesMV(simpleModel, nodes = 'x', mv = mv)
rGetLogProbMany <- getLogProbNodesMV(simpleModel,
                                     nodes = 'x', mv = mv)

cSimManyXY <- compileNimble(rSimManyXY, project = simpleModel)
cCalcManyXDeps <- compileNimble(rCalcManyXDeps, project = simpleModel)

```

```

cGetLogProbMany <- compileNimble(rGetLogProbMany, project = simpleModel)

cSimManyXY$run(m = 5) # simulating 5 times

## NULL

cCalcManyXDepts$run(saveLP = TRUE) # calculating

## [1] -19.36889 -21.39145 -14.71200 -10.72175 -11.67675

cGetLogProbMany$run() #

## [1] -19.36889 -21.39145 -14.71200 -10.72175 -11.67675

```

8.2 Particle Filter

NIMBLE includes an algorithm for a basic particle filter to be used for approximating the log likelihood of a state-space model. A particle filter can be built for such a model by a call to `buildPF`. This nimbleFunction requires setup arguments `model` and `nodes`, which is a character vector specifying latent model nodes. The particle filter can be run by specifying the number of particles.

Here is an example, using a linear state-space model for which we can also calculate the likelihood using the Kalman Filter to verify if the particle filter seems to be working.

```

# Building a simple linear state-space model.
# x is latent space, y is observed data
timeModelCode <- nimbleCode({
  x[1] ~ dnorm(mu_0, 1)
  y[1] ~ dnorm(x[1], 1)
  for(i in 2:t){
    x[i] ~ dnorm(x[i-1] * a + b, 1)
    y[i] ~ dnorm(x[i] * c, 1)
  }

  a ~ dunif(0, 1)
  b ~ dnorm(0, 1)
  c ~ dnorm(1,1)
  mu_0 ~ dnorm(0, 1)
})

#simulate some data
t = 25; mu_0 = 1
x = rnorm(1 ,mu_0, 1)

```

```

y = rnorm(1, x, 1)
a = 0.5; b = 1; c = 1
for(i in 2:t){
  x[i] = rnorm(1, x[i-1] * a + b, 1)
  y[i] = rnorm(1, x[i] * c, 1)
}
## build and compile the model
rTimeModel <- nimbleModel(timeModelCode, constants = list(t = t),
  data = list(y = y), check = FALSE )

## defining model...
## building model...
## setting data and initial values...
## model building finished

cTimeModel <- compileNimble(rTimeModel)

#Build the particle filter
rPF <- buildPF(rTimeModel, "x")
cPF = compileNimble(rPF,project = rTimeModel)

#Set parameter values
cTimeModel$mu_0 = 1
cTimeModel$a = 0.5
cTimeModel$b = 1
cTimeModel$c = 1
cTimeModel$mu_0 = 1

#Run particle filter with
#5000 particles
cPF$run(m = 5000)

## [1] -42.54816

```

8.3 Monte Carlo Expectation Maximization (MCEM)

Suppose we have a model with missing data (or a layer of latent variables that can be treated as missing data) and we would like to maximize the marginal likelihood of the model, integrating over the missing data. A brute-force method for doing this is MCEM. This is an EM algorithm in which the missing data are simulated via Monte Carlo (often MCMC, when the full conditional distributions cannot be directly sampled from) at each iteration. MCEM can be slow, and there are other methods for maximizing marginal likelihoods that can be implemented in NIMBLE. The reason we started with MCEM is to explore the flexibility of

NIMBLE and illustrate the combination of R and NIMBLE involved, with R managing the highest-level processing of the algorithm and calling `nimbleFunctions` for computations.

We will revisit the *pump* example to illustrate the use of NIMBLE’s MCEM algorithm.

```
## defining model...
## building model...
## setting data and initial values...
## checking model... (use nimbleModel(..., check = FALSE) to skip model check)
## model building finished
```

```
pumpMCEM <- buildMCEM(model = newPump,
  latentNodes = 'theta',
  burnIn = 100,
  mcmcControl = list(adaptInterval = 20),
  boxConstraints = list( list( c('alpha', 'beta'),
    limits = c(0, Inf) ) ),
  buffer = 1e-6)
```

Here `newPump` was created just like `pump` in Section 2.2. The first argument, `model`, is a NIMBLE model, which can be either the uncompiled or compiled version. At the moment, the model provided cannot be part of another MCMC sampler.

The `latentNodes` argument should indicate the nodes that will be integrated over (sampled via MCMC), rather than maximized. These nodes must be stochastic, not deterministic! `latentNodes` will be expanded as described in Section 6.4.1: e.g., either `latentNodes = 'x'` or `latentNodes = c('x[1]', 'x[2]')` will treat `x[1]` and `x[2]` as latent nodes if `x` is a vector of two values. All other non-data nodes will be maximized over. Note that `latentNodes` can include discrete nodes, but the nodes to be maximized cannot.

The `burnIn` argument indicates the number of samples from the MCMC for the E-step that should be discarded when computing the expected likelihood in the M-step. Note that `burnIn` can be set to values lower than in standard MCMC computations, as each iteration will start off where the last left off.

The `mcmcControl` argument will be passed to `configureMCMC` to define the MCMC to be used.

The MCEM algorithm allows for box constraints on the nodes that will be optimized, specified via the `boxConstraints` argument. This is highly recommended for nodes that have zero density on parts of the real line¹. Each constraint given should be a list in which the first element is the names of the nodes or variables that the constraint will be applied to and the second element is a vector of length 2, in which the first value is the lower limit and the second is the upper limit. Values of `Inf` and `-Inf` are allowed. If a node is not listed, it will be assumed that there are no constraints. These arguments are passed as `lower` and `upper` to R’s `optim` function, using `method = 'L-BFGS-B'`

¹Currently NIMBLE does not determine this automatically.

The value of the `buffer` argument shrinks the `boxConstraints` by this amount. This can help protect against non-finite values occurring when a parameter is on its boundary value.

Once the MCEM has been built for the model of interest using `buildMCEM`, it can be run as follows.

```
pumpMCEM(maxit = 20, m1 = 250, m2 = 500)

##      alpha      beta
## 0.817552 1.256396

pumpMCEM(maxit = 50, m1 = 1000, m2 = 5000)

##      alpha      beta
## 0.8236072 1.2673791
```

There are three run-time arguments:

The `maxit` argument is the number of total iterations to run the algorithm. More advanced MCEM algorithms have a stopping criteria based on computing the MCMC error. Our current draft implementation of the algorithm merely runs `maxit` iterations and then terminates.

Halfway through the algorithm, the sample size used for the E-step switches from `m1` to `m2`. This provides smaller MCMC error as the algorithm converges. If `m1` or `m2` is less than or equal to `burnIn` as defined in `build_MCEM`, the MCEM algorithm will immediately quit.

When using the MCEM algorithm, we suggest first starting with small values of `m1` and `m2` to get an estimate of how long the algorithm will take for larger MCMC samples. The speed of the algorithm will be linear in `m2` (assuming that $m2 > m1$ as intended).

Chapter 9

Writing nimbleFunctions

9.1 Writing nimbleFunctions

When you write an R function, you say what the input arguments are, you provide the code for execution, and in that code you give the returned value¹. Using the `function` keyword in R triggers the operation of creating an object that is the function.

Creating `nimbleFunctions` is similar, but there are two kinds of code and two steps of execution:

1. **Setup** code is provided as a regular R function, but the programmer does not control what it returns. Typically the inputs to `setup` code are objects like a model, a vector of nodes, a `modelValues` object or `modelValuesSpec`, or another `nimbleFunction`. The `setup` code, as its name implies, sets up information for run-time code. It is executed in R, so it can use any aspect of R.
2. **Run** code is provided in the NIMBLE language. This is similar to a narrow subset of R, but it is important to remember that it is different – defined by what can be compiled – and much more limited. **Run** code can use the objects created by the `setup` code. In addition, some information on variable types must be provided for input arguments, the return object, and in some circumstances for local variables. There are two kinds of `run` code:
 - (a) There is always a primary function, given as an argument called `run`².
 - (b) There can optionally be other functions, or “methods” in the language of object-oriented programming, that share the same objects created by the `setup` function.

Here is a small example to fix ideas:

```
logProbCalcPlus <- nimbleFunction(  
  setup = function(model, node) {  
    dependentNodes <- model$getDependencies(node)  
    valueToAdd <- 1
```

¹normally the value of the last evaluated code, or the argument to `return()`.

²This can be omitted if you don't need it.

```

    },

    run = function(P = double(0)) {
      model[[node]] <<- P + valueToAdd
      return(calculate(model, dependentNodes))
      returnType(double(0))
    })

code <- nimbleCode({
  a ~ dnorm(0, 1); b ~ dnorm(a, 1)
})
testModel <- nimbleModel(code, check = FALSE)

## defining model...
## building model...
## model building finished

logProbCalcPlusA <- logProbCalcPlus(testModel, 'a')
testModel$b <- 1.5
logProbCalcPlusA$run(0.25)

## [1] -2.650377

dnorm(1.25,0,1,TRUE)+dnorm(1.5,1.25,1,TRUE) ## direct validation

## [1] -2.650377

testModel$a ## a was set to 0.5 + valueToAdd

## [1] 1.25

```

The call to the R function called `nimbleFunction` returns a function, similarly to defining a function in R. That function, `logProbCalcPlus`, takes arguments for its `setup` function, executes it, and returns an object, `logProbCalcPlusA`, that has a `run` member function (method) accessed by `$run`. In this case, the `setup` function obtains the stochastic dependencies of the `node` using the `getDependencies` member function of the model (see Section 6.5.2) and stores them in `dependentNodes`. In this way, `logProbCalcPlus` can adapt to any model. It also creates a variable, `valueToAdd`, that can be used by the `nimbleFunction`.

The object `logProbCalcPlusA`, returned by `logProbCalcPlus`, is permanently bound to the results of the processed `setup` function. In this case, `logProbCalcPlusA$run` takes a scalar input value, `P`, assigns `P + valueToAdd` to the given node in the model, and returns the sum of the log probabilities of that node and its stochastic dependencies³. We say

³Note the use of the global assignment operator to assign into the model. This is necessary for assigning into variables from the `setup` function, at least if you want to void warnings from R. These warnings come from R's reference class system.

`logProbCalcPlusA` is an “instance” of `logProbCalcPlus` that is “specialized” or “bound” to `a` and `testModel`. Usually, the `setup` code will be where information about the model structure is determined, and then the `run` code can use that information without repeatedly, redundantly recomputing it. A `nimbleFunction` can be called repeatedly, each time returning a specialized `nimbleFunction`.

Readers familiar with object-oriented programming may find it useful to think in terms of class definitions and objects. `nimbleFunction` creates a class definition. Each specialized `nimbleFunction` is one object in the class. The `setup` arguments are used to define member data in the object.

9.2 Using and compiling `nimbleFunction`s

To compile the `nimbleFunction`, together with its model, we use `compileNimble`:

```
CnfDemo <- compileNimble(testModel, logProbCalcPlusA)
CtestModel <- CnfDemo$testModel
ClogProbCalcPlusA <- CnfDemo$logProbCalcPlusA
```

These have been initialized with the values from their uncompiled versions and can be used in the same way:

```
CtestModel$a      ## values were initialized from testModel
## [1] 1.25

CtestModel$b

## [1] 1.5

lpA <- ClogProbCalcPlusA$run(1.5)
lpA

## [1] -5.462877

## verify the answer:
dnorm(CtestModel$b, CtestModel$a, 1, log = TRUE) +
  dnorm(CtestModel$a, 0, 1, log = TRUE)

## [1] -5.462877

CtestModel$a      ## a was modified in the compiled model
## [1] 2.5

testModel$a       ## the uncompiled model was not modified
## [1] 1.25
```

9.2.1 Accessing and modifying numeric values from setup

While models and nodes created during `setup` cannot be modified⁴, numeric values and `modelValues` (see below) can be. For example:

```
logProbCalcPlusA$valueToAdd ## in the uncompiled version

## [1] 1

logProbCalcPlusA$valueToAdd <- 2
ClogProbCalcPlusA$valueToAdd ## or in the compiled version

## [1] 1

ClogProbCalcPlusA$valueToAdd <- 3
ClogProbCalcPlusA$run(1.5)

## [1] -16.46288

CtestModel$a ## a == 1.5 + 3

## [1] 4.5
```

9.3 nimbleFunctions without setup code

The `setup` function is optional. If it is omitted, then `nimbleFunction` is more like `function`: it simply returns a function that can be executed and compiled. If there is no `setup` code, there is no specialization step. This is useful for doing math or the other kinds of processing available in NIMBLE when no model or `modelValues` is needed.

```
solveLeastSquares <- nimbleFunction(
  run = function(X = double(2), y = double(1)) {
    ans <- inverse(t(X) %*% X) %*% (t(X) %*% y)
    return(ans)
    returnType(double(2))
  } )

X <- matrix(rnorm(400), nrow = 100)
y <- rnorm(100)
solveLeastSquares(X, y)

##           [,1]
## [1,] -0.1559144
```

⁴Actually, they can be, but only for uncompiled `nimbleFunctions`

```
## [2,] -0.1874887

## [4,] -0.1063246

CsolveLeastSquares <- compileNimble(solveLeastSquares)
CsolveLeastSquares(X, y)

##           [,1]
## [1,] -0.1559144
## [2,] -0.1874887
## [3,]  0.1541508
## [4,] -0.1063246
```

This example shows the textbook calculation of a least squares solution for regression of 100 data points on 4 explanatory variables, all generated randomly⁵. Such functions can be called from other nimbleFunctions or used in BUGS code.⁶

If one wants a nimbleFunction that does get specialized but has empty setup code, use `setup = function() {}` or `setup = TRUE`.

9.4 Useful tools for setup functions

The setup function is typically used to determine information on nodes in a model, set up any modelValues objects, set up any nimbleFunctions or nimbleFunctionLists, and set up any persistent numeric objects. For example, the `setup` code of an MCMC nimbleFunction creates the nimbleFunctionList of sampler nimbleFunctions. The values of numeric objects created in `setup` can be modified by run code and will persist across calls.

Some of the useful tools and objects to create in `setup` functions include

vectors of node names Often these are obtained from the `getNodeNames` and `getDependencies` methods of a model, described in Section 6.5.1.

modelValues objects These are discussed more below.

specializations of other nimbleFunctions A useful NIMBLE programming technique is to have one nimbleFunction contain other nimbleFunctions, which it can use in its run-time code.

lists of other nimbleFunctions In addition to containing single other nimbleFunctions, a nimbleFunction can contain a list of other nimbleFunctions. These are discussed more below.

⁵Of course in general, explicitly calculating the inverse is not the recommended numerical recipe for least squares.

⁶On the machine this is being written on, the compiled version runs a few times faster than the uncompiled version. However we refrain from formal speed tests.

9.4.1 Control of setup outputs

Sometimes `setup` code may create variables that are not used in run-time code. By default, NIMBLE inspects run-time code and omits variables from `setup` that do not appear in run-time code from compilation. However, sometimes a programmer may want to force a numeric or character variable to be created in compilation, even if it is not used directly in run-time code. As shown below, such variables can be directly accessed in one `nimbleFunction` from another, which provides a way of using `nimbleFunctions` as general data structures. To force NIMBLE to include variables around during compilation, for example `X` and `Y`, simply include

```
setupOutputs(X, Y)
```

anywhere in the `setup` code.

9.5 NIMBLE language components

9.5.1 Basics

There are several general points that will be useful before describing the NIMBLE language in more detail.

- NIMBLE language functions are not R functions. In many cases we have used syntax identical or nearly so to R, and in most cases we have provided a matching R function, but it is important not to confuse the NIMBLE language definition with the behavior of the corresponding R function.
- As in R, function calls in NIMBLE can provide arguments by name or in a default order.
- Like R, NIMBLE uses 1-based indexing. For example, the first element of a vector `x` is `x[1]`, not `x[0]`.
- To a large extent, NIMBLE functions can be executed in R (uncompiled) or can be compiled. Using them in R will be slow, and is intended for testing and debugging algorithm logic.
- NIMBLE is the opposite of R for argument passing. R nearly always uses pass-by-value. NIMBLE nearly always uses pass-by-reference (or pointer). That means that in compiled execution only, changing the value of a variable that was a function input will change the value in the calling function. Thus it is possible to write a `nimbleFunction` that returns information by modifying an argument. Yes, that's a big difference in behavior!

Although compiled `nimbleFunctions` can modify arguments, the R interface to a compiled `nimbleFunction` performs a copy to protect the original R argument from modification. (If you want to see arguments – potentially modified – as well as any return value from R, you can modify the `control` argument to `compileNimble` to include “`returnAsList = TRUE`”. Then the returned object will be a list with the `nimbleFunction`'s return value as the last element.)

```

                                sizes = 1)
savedWeights <- modelValues(spec = savedWeightsSpec)
## List of nodes to be used in run function
modelNodes <- model$getNodeNames(stochOnly = TRUE,
                                includeData = FALSE)
}

```

The simplest way to pass values back and forth between models and `modelValues` inside of a `nimbleFunction` is with `copy`, which has the synonym `nimCopy`. See `help(nimCopy)` for argument details.

Alternatively, the values may be accessed via indexing of individual rows, using the notation `mv[var, i]`, where `mv` is a `modelValues` object, `var` is a variable name (not a node name), and `i` is a row number. Likewise, the `getsize` and `resize` functions can be used as discussed previously. However the function `as.matrix` does not work in `run` code.

Here is a `run` function to use these `modelValues`:

```

runFunction = function(){
  ## gets the number of rows of propSamples
  m <- getsize(propModelValues)

  ## resized savedWeights to have the proper rows
  resize(savedWeights, m)
  for(i in 1:m){
    ## Copying from propSamples to model.
    ## Node names of propSamples and model must match!
    nimCopy(from = propModelValues, to = model, row = i,
            nodes = modelNodes, logProb = FALSE)
    ## calculates the log likelihood of the model
    targLL <- calculate(model)
    ## retrieves the saved log likelihood from the proposed model
    propLL <- propModelValues['propLL',i][1]
    ## saves the importance weight for the i-th sample
    savedWeights['w', i][1] <<- exp(targLL - propLL)
  }
  ## does not return anything
}

```

Once the `nimbleFunction` is built, the `modelValues` object can be accessed using `$`, which is shown in more detail below. In fact, since `modelValues`, like most NIMBLE objects, are reference class objects, one can get a reference to them before the function is executed and then use that reference afterwards.

```

## Simple model and modelValue for example
targetModelCode <- nimbleCode({

```

```

    x ~ dnorm(0,1)
    for(i in 1:4)
      y[i] ~ dnorm(0,1)
  })

## Code for proposal model
propModelCode <- nimbleCode({
  x ~ dnorm(0,2)
  for(i in 1:4)
    y[i] ~ dnorm(0,2)
})

## Building R models
targetModel = nimbleModel(targetModelCode, check = FALSE)

## defining model...
## building model...
## model building finished

propModel = nimbleModel(propModelCode, check = FALSE)

## defining model...
## building model...
## model building finished

cTargetModel = compileNimble(targetModel)
cPropModel = compileNimble(propModel)

sampleMVSpec = modelValuesSpec(vars = c('x', 'y', 'propLL'),
  types = c('double', 'double', 'double'),
  sizes = list(x = 1, y = 4, propLL = 1) )

sampleMV <- modelValues(sampleMVSpec)

## nimbleFunction for generating proposal sample
PropSamp_Gen <- nimbleFunction(
  setup = function(mv, propModel){
    nodeNames <- propModel$getNodeNames()
  },
  run = function(m = integer() ){
    resize(mv, m)
    for(i in 1:m){
      simulate(propModel)
      nimCopy(from = propModel, to = mv, nodes = nodeNames, row = i)
      mv['propLL', i][1] <<- calculate(propModel)
    }
  }
)

```

```

    }
  }
)

## nimbleFunction for calculating importance weights
## Recylcing setupFunction and runFunction as defined in earlier example
impWeights_Gen <- nimbleFunction(setup = setupFunction,
                                run = runFunction)

## Making instances of nimbleFunctions
## Note that both functions share the same modelValues object
RPropSamp <- PropSamp_Gen(sampleMV, propModel)
RImpWeights <- impWeights_Gen(sampleMV, targetModel)

# Compiling
CPropSamp <- compileNimble(RPropSamp, project = propModel)
CImpWeights <- compileNimble(RImpWeights, project = targetModel)

#Generating and saving proposal sample of size 10
CPropSamp$run(10)

## NULL

## Calculating the importance weights and saving to mv
CImpWeights$run()

## NULL

## Retrieving the modelValues objects
## Extracted objects are C-based modelValues objects

savedPropSamp_1 = CImpWeights$propModelValues
savedPropSamp_2 = CPropSamp$mv

# Subtle note: savedPropSamp_1 and savedPropSamp_2
# both provide interface to the same compiled modelValues objects!
# This is because they were both built from sampleMV.

```

Importance sampling could also be written using simple vectors for the weights, but we illustrated putting them in a `modelValues` object along with model variables.

9.5.5 Using model variables and modelValues in expressions

Each way of accessing a variable, node, or `modelValues` can be used amid mathematical expressions, including with indexing, or passed to another `nimbleFunction` as an argument. For example, the following two statements would be valid:

```
model[['x[2:8, ]']] [2:4, 1:3] %*% Z
```

if `Z` is a vector or matrix, and

```
C[6:10] <- mv[v, i] [1:5, k] + B
```

if `B` is a vector or matrix.

The NIMBLE language allows scalars, but models defined from BUGS code are never created as purely scalar nodes. Instead, a single node such as defined by $z \sim \text{dnorm}(0, 1)$ is implemented as a vector of length 1, similar to R. When using `z` via `model$z` or `model[['z']]`, NIMBLE will try to do the right thing by treating this as a scalar. In the event of problems⁷, a more explicit way to access `z` is `model$z[1]` or `model[['z']][1]`.

⁷please tell us!

9.5.6 Getting and setting more than one model node or variable at a time using values

Sometimes it is useful to set a collection of nodes or variables at one time. For example, one might want a nimbleFunction that will serve as the objective function for an optimizer. The input to the nimbleFunction would be a vector, which should be used to fill a collection of nodes in the model before calculating their log probabilities. NIMBLE has two ways to do this, one of which was set up during development and may be deprecated in the future.

The recommended newer way is:

```
P <- values(model, nodes)
values(model, nodes) <- P
```

where the first line would assign the collection of values from nodes into P, and the second would do the inverse. In both cases, values from nodes with 2 or more dimensions are flattened into a vector in column-wise order.

The older syntax, which may be deprecated in the future, is

```
getValues(P, model, nodes)
setValues(P, model, nodes)
```

These are equivalent to the two previous lines. Note that `getValues` modifies P in the calling environment.

With the new notation, `values(model, nodes)` may appear as a vector in other expressions, e.g. `Y <- A %*% values(model, nodes) + b`.

9.5.7 Basic flow control: if-then-else, for, and while

These basic control flow structures use the same syntax as in R. However, `for`-loops are limited to sequential integer indexing. For example, `for(i in 2:5) {...}` works as it does in R. Decreasing index sequences are not allowed.

We plan to include more flexible `for`-loops in the future, but for now we've included just one additional useful feature: `for(i in seq_along(NFL))` will work as in R, where NFL is a `nimbleFunctionList`. This is described below.

9.5.8 How numeric types work

Numeric types in NIMBLE are much less flexible than in R, a reflection of the fact that NIMBLE code can be compiled into C++⁸. In NIMBLE, the *type* of a numeric object refers to the number of dimensions and the numeric type of the elements. In v0.4, objects from 0 (scalar) to 4 dimensions are supported, and the numeric types integer and double are supported. In addition the type logical is supported for scalars only. While the number of dimensions cannot change during run-time, numeric objects can be resized using `setSize` or by full (non-indexed) assignment.

⁸C++ is a statically typed language, which means the type of a variable cannot change.

When possible, NIMBLE will determine the type of a variable for you. In other cases you must declare the type. The rules are as follows:

- For numeric variables from the `setup` function that appear in the `run` function or other member functions (or are declared in `setupOutputs`): the type is determined from the values created by the `setup` code. The types created by `setup` code must be consistent across all specializations of the `nimbleFunction`. For example if `X` is created as a matrix (2-dimensional double) in one specialization but as a vector (1-dimensional double) in another, there will be a problem during compilation. The sizes may differ in each specialization.
Treatment of vectors of length 1 presents special challenges because they could be treated as scalars or vectors. Currently they are treated as scalars. If you want a vector, ensure that the length is greater than 1 in the `setup` code and then use `setSize` in the run-time code.
- In `run` code, when a numeric variable is created by assignment, its type is determined by that assignment. Subsequent uses of that variable must be consistent with that type.
- If the first uses of a variable involves indexing, the type must be declared explicitly, using `declare`, before using it. In addition, its size must be set before assigning into it. Sizes can be included in the `declare()` statement, but if so they should not subsequently change. If a variable may have its size changed during execution, then the `declare` statement should omit the size argument, and a separate call to `setSize` should be used to set the initial size(s).

9.5.9 Querying and changing sizes

Sizes can be queried as follows:

- `length` behaves like R's `length` function. It returns the *entire* length of `X`. That means if `X` is multivariate, `length` returns the product of the sizes in each dimension.
- `dim`, which has synonym `nimDim`, behaves like R's `dim` function for matrices or arrays, and like R's `length` function for vectors. In other words, regardless of whether the number of dimensions is 1 or more, it returns a vector of the sizes. Using `dim` vs. `nimDim` is a personal choice, but if you use `dim`, you should keep in mind that it behaves differently from R's `dim`.
 - A quirky limitation in v0.4: It not currently possible to assign the results from `nimDim` to another object using vector assignment. So the only practical way to use `nimDim` is to extract elements immediately, such as `nimDim(X)[1]`, `nimDim(X)[2]`, etc.

Sizes can be changed using:

- `setSize(X, size1, size2, ...)`

where `size1`, `size2` etc. provide the sizes of as many dimensions as needed by `X`.

9.5.10 Basic math and linear algebra

NIMBLE uses the *Eigen* library in C++ to accomplish linear algebra. In v0.4, we use a lot of Eigen’s capabilities, but not all of them. The supported operations are given in Tables 5.4-5.5.

No vectorized operations other than assignment are supported for more than two dimensions in v0.4. That means $A = B + C$ will work only if B and C have dimensions ≤ 2 .

Managing dimensions and sizes: `asRow`, `asCol`, and dropping dimensions

It can be tricky to determine the dimensions returned by a linear algebra expression. As much as possible, NIMBLE behaves like R, but in some cases this is not possible because R uses run-time information while NIMBLE must determine dimensions at compile-time.

Suppose `v1` and `v2` are vectors, and `M1` is a matrix. Then

- `v1 + M1` generates a compilation error unless one dimension of `M1` is known at compile-time to be 1. If so, then `v1` is promoted to a 1-row or 1-column matrix to conform with `M1`, and the result is a matrix of the same sizes. This behavior occurs for all component-wise binary functions.
- `v1 %*% M1` defaults to promoting `v1` to a 1-row matrix, unless it is known at compile-time that `M1` has 1 row, in which case `v1` is promoted to a 1-column matrix.
- `M1 %*% v1` defaults to promoting `v1` to a 1-column matrix, unless it is known at compile time that `M1` has 1 column, in which case `v1` is promoted to a 1-row matrix.
- `v1 %*% v2` promotes `v1` to a 1-row matrix and `v2` to a 1-column matrix, so the returned values is a 1x1 matrix with the inner product of `v1` and `v2`.
- `asRow(v1)` explicitly promotes `v1` to a 1-row matrix. Therefore `v1 %*% asRow(v2)` gives the outer product of `v1` and `v2`.
- `asCol(v1)` explicitly promotes `v1` to a 1-column matrix.
- The default promotion for a vector is to a 1-column matrix. Therefore, `v1 %*% t(v2)` is equivalent to `v1 %*% asRow(v2)`.
- When indexing, dimensions with scalar indices will be dropped. For example, `M1[1,]` and `M1[,1]` are both vectors.
- The left-hand side of an assignment can use indexing, but if so it must already be correctly sized for the result. For example, `Y[5:10, 20:30] <- model$x` will not work – and could crash your R session with a segmentation fault – if `Y` is not already at least 10x30 in size.

Here are some examples to illustrate the above points, assuming `M2` is a square matrix.

- `Y <- v1 + M2 %*% v2` will return a 1-column matrix. If `Y` is created by this statement, it will be a 2-dimensional variable. If `Y` already exists, it must already be 2-dimensional, and it will be automatically re-sized for the result.
- `Y <- v1 + (M2 %*% v2)[,1]` will return a vector. `Y` will either be created as a vector or must already exist as a vector and will be re-sized for the result.

Size warnings and the potential for crashes

For matrix algebra, NIMBLE cannot ensure perfect behavior because sizes are not known until run-time. Therefore, it is possible for you to write code that will crash your R session. In v0.4, NIMBLE attempts to issue warning if sizes are not compatible, but it does not halt execution. Therefore, if you execute `A <- M1 % * % M2`, and M1 and M2 are not compatible for matrix multiplication, NIMBLE will output a warning that the number of rows of M1 does not match the number of columns of M2. After that warning the statement will be executed and may result in a crash. Another easy way to write code that will crash is to do things like `Y[5:10, 20:30] <- model$x` without ensuring Y is at least 10x30. In the future we hope to prevent crashes, but in v0.4 we limit ourselves to trying to provide useful information.

9.5.11 Including other methods in a nimbleFunction

Other methods can be included with the `methods` argument to `nimbleFunction`. These methods can use the objects created in `setup` code in just the same ways as the `run` function. In fact, the `run` function is just a default main method name.

```

methodsDemo <- nimbleFunction(
  setup = function() {sharedValue <- 1},
  run = function(x = double(1)) {
    print('sharedValues = ', sharedValue, '\n')
    increment()
    print('sharedValues = ', sharedValue, '\n')
    A <- times(5)
    return(A * x)
    returnType(double(1))
  },
  methods = list(
    increment = function() {
      sharedValue <<- sharedValue + 1
    },
    times = function(factor = double()) {
      return(factor * sharedValue)
      returnType(double())
    }
  ))

methodsDemo1 <- methodsDemo()
methodsDemo1$run(1:10)

## sharedValues = 1
##
## sharedValues = 2
## [1] 10 20 30 40 50 60 70 80 90 100

```

```

methodsDemo1$sharedValue <- 1
CmethodsDemo1 <- compileNimble(methodsDemo1)
CmethodsDemo1$run(1:10)

## sharedValues = 1
##
## sharedValues = 2
## [1] 10 20 30 40 50 60 70 80 90 100

```

9.5.12 Using other nimbleFunctions

One nimbleFunction can use another nimbleFunction that was passed to it as a setup argument or was created in the setup function. This can be an effective way to program. When a nimbleFunction needs to access a setup variable or method of another nimbleFunction, use \$.

```

usePreviousDemo <- nimbleFunction(
  setup = function(initialSharedValue) {
    myMethodsDemo <- methodsDemo()
  },
  run = function(x = double(1)) {
    myMethodsDemo$sharedValue <<- initialSharedValue
    print(myMethodsDemo$sharedValue)
    A <- myMethodsDemo$run(x[1:5])
    print(A)
    B <- myMethodsDemo$times(10)
    return(B)
    returnType(double())
  })

usePreviousDemo1 <- usePreviousDemo(2)
usePreviousDemo1$run(1:10)

## 2
## sharedValues = 2
##
## sharedValues = 3
##
## 15 30 45 60 75
## [1] 30

CusePreviousDemo1 <- compileNimble(usePreviousDemo1)
CusePreviousDemo1$run(1:10)

```

```
## 2
## sharedValues = 2
##
## sharedValues = 3
##
## 15
## 30
## 45
## 60
## 75
## [1] 30
```

Note that the output from the `print` calls in the compiled function match those from the uncompiled function when run in an R session. It may not be shown here because this document is created with `knitr` and for some reason output printed from C++ does not make it into `knitr` output.

9.5.13 Virtual `nimbleFunctions` and `nimbleFunctionLists`

Often it is useful for one `nimbleFunction` to have a list of other `nimbleFunctions` that have methods with the same arguments and return types. For example, NIMBLE’s MCMC contains a list of samplers that are each `nimbleFunctions`.

To make such a list, NIMBLE provides a way to declare the arguments and return types of methods: virtual `nimbleFunctions` created by `nimbleFunctionVirtual`. Other `nimbleFunctions` can inherit from virtual `nimbleFunctions`, which in R is called “containing” them. Readers familiar with object oriented programming will recognize this as a simple class inheritance system. In v0.4 it is limited to simple, single-level inheritance.

Here is how it works:

```
baseClass <- nimbleFunctionVirtual(
  run = function(x = double(1)) {returnType(double())},
  methods = list(
    foo = function() {returnType(double())}
  ))

derived1 <- nimbleFunction(
  contains = baseClass,
  setup = function() {},
  run = function(x = double(1)) {
    print('run 1')
    return(sum(x))
    returnType(double())
  },
  methods = list(
```

```
    foo = function() {
      print('foo 1')
      return(rnorm(1, 0, 1))
      returnType(double())
    })

derived2 <- nimbleFunction(
  contains = baseClass,
  setup = function() {},
  run = function(x = double(1)) {
    print('run 2')
    return(prod(x))
    returnType(double())
  },
  methods = list(
    foo = function() {
      print('foo 2')
      return(runif(1, 100, 200))
      returnType(double())
    })

useThem <- nimbleFunction(
  setup = function() {
    nfl <- nimbleFunctionList(baseClass)
    nfl[[1]] <- derived1()
    nfl[[2]] <- derived2()
  },
  run = function(x = double(1)) {
    for(i in seq_along(nfl)) {
      print( nfl[[i]]$run(x) )
      print( nfl[[i]]$foo() )
    }
  }
)

useThem1 <- useThem()
set.seed(0)
useThem1$run(1:5)

## run 1
## 15
## foo 1
## 1.262954
## run 2
## 120
```

```
## foo 2
## 137.2124

CuseThem1 <- compileNimble(useThem1)
set.seed(0)
CuseThem1$run(1:5)

## run 1
## 15
## foo 1
## 1.26295
## run 2
## 120
## foo 2
## 137.212
## NULL
```

As in R, the `seq_along` function is equivalent to `1:length(nimFunList)` if `length(nimFunList) > 0`, and it is an empty sequence if `length(nimFunList) == 0`.

Currently `seq_along` works only for `nimbleFunctionLists`.

Virtual `nimbleFunctions` cannot define `setup` values to be inherited.

9.5.14 print and stop

As demonstrated above, the NIMBLE function `print`, or equivalently `nimPrint`, prints an arbitrary set of outputs in order. The NIMBLE function `stop`, or equivalently `nimStop`, throws control to R's error-handling system and can take one string (character) argument.

9.5.15 Checking for user interrupts

When you write algorithms that will run for a long time in C++, you may want to explicitly check whether a user has tried to interrupt the execution (e.g. by pressing Control-C). Simply include `checkInterrupt()` in `run` code to do so. If there has been an interrupt, the process with `stop` and return control to R.

9.5.16 Character objects

NIMBLE provides limited uses of character objects in `run` code. Character vectors created in `setup` code will be available in `run` code, but the only thing you can really do with them is include them in a `print` or `stop` statement.

Note that character vectors of model node and variable names are processed during compilation. For example, in `model[[node]]`, `node` may be a character object, and the NIMBLE compiler processes this differently than `print('The node name was ', node)`. In the former, the NIMBLE compiler sets up a C++ pointer directly to the `node` in the `model`,

so that the character content of `node` is never needed in C++. In the latter, `node` is used as a C++ string and therefore is needed in C++.

9.5.17 Alternative keywords for some functions

NIMBLE uses some keywords, such as `dim` and `print`, in ways similar but not identical to R. In addition, there are some keywords in NIMBLE that have the same names as really different R functions. For example, `step` is part of the BUGS language, but it is also an R function for stepwise model selection. And `equals` is part of the BUGS language but is also used in the `testthat` package, which we use in testing NIMBLE.

The way NIMBLE handles this to try to avoid conflicts is to replace some keywords immediately upon creating a `nimbleFunction`. These replacements include

- `copy` → `nimCopy`
- `dim` → `nimDim`
- `print` → `nimPrint`
- `step` → `nimStep`
- `equals` → `nimEquals`
- `round` → `nimRound`
- `stop` → `nimStop`

This system gives programmers the choice between using the keywords like `nimPrint` directly, to avoid confusion in their own code about which “print” is being used, or to use the more intuitive keywords like `print` but remember that they are not the same as R’s functions.

9.5.18 User-defined data structures

NIMBLE does not explicitly have user-defined data structures, but one can use `nimbleFunction`s to achieve a similar effect. To do so, one can define setup code with whatever variables are wanted and ensure they are compiled using `setupOutputs`. Here is an example:

```
dataNF <- nimbleFunction(
  setup = function() {
    X <- 1
    Y <- as.numeric(c(1, 2)) ## will be a scalar if all sizes are 1
    Z <- matrix(as.numeric(1:4), nrow = 2) ## will be a scalar is all sizes are 1
    setupOutputs(X, Y, Z)
  })

useDataNF <- nimbleFunction(
  setup = function(myDataNF) {},
  run = function(newX = double(), newY = double(1), newZ = double(2)) {
    myDataNF$X <- newX
    myDataNF$Y <- newY
  })
```

```

    myDataNF$Z <- newZ
  })

myDataNF <- dataNF()
myUseDataNF <- useDataNF(myDataNF)
myUseDataNF$run(as.numeric(100), as.numeric(100:110), matrix(as.numeric(101:120), nrow = 2))
myDataNF$X

## [1] 100

myDataNF$Y

## [1] 100 101 102 103 104 105 106 107 108 109 110

myDataNF$Z

##      [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10]
## [1,]  101  103  105  107  109  111  113  115  117  119
## [2,]  102  104  106  108  110  112  114  116  118  120

myUseDataNF$myDataNF$X

## [1] 100

nimbleOptions(useMultiInterfaceForNestedNimbleFunctions = FALSE)
CmyUseDataNF <- compileNimble(myUseDataNF)
CmyUseDataNF$run(-100, -(100:110), matrix(-(101:120), nrow = 2))

## NULL

CmyDataNF <- CmyUseDataNF$myDataNF
CmyDataNF$X

## [1] -100

CmyDataNF$Y

## [1] -100 -101 -102 -103 -104 -105 -106 -107 -108 -109 -110

CmyDataNF$Z

##      [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10]
## [1,] -101 -103 -105 -107 -109 -111 -113 -115 -117 -119
## [2,] -102 -104 -106 -108 -110 -112 -114 -116 -118 -120

```

You'll notice that:

- After execution of the compiled function, access to the X, Y, and Z is the same as for the uncompiled case. This occurs because `CmyUseDataNF` is an interface to the compiled version of `myUseDataNF`, and it provides access to member objects and functions. In this case, one member object is `myDataNF`, which is an interface to the compiled version of `myUseDataNF$myDataNF`, which in turn provides access to X, Y, and Z. To reduce memory use, NIMBLE defaults to *not* providing full interfaces to nested nimbleFunctions like `myUseDataNF$myDataNF`. In this example we made it provide a full interfaces by setting the `useMultiInterfaceForNestedNimbleFunctions` option via `nimbleOptions` as shown. If we had left that option `TRUE` (its default value), we could still get to the values of interest using

```
valueInCompiledNimbleFunction(CmyDataNF, 'X')
```

- We need to take care that at the time of compilation, the X, Y and Z values contain doubles via `as.numeric` so that they are not compiled as integer objects.
- The `myDataNF` could be created in the setup code. We just provided it as a setup argument to illustrate that option.

9.5.19 Distribution functions

Distribution “d”, “r”, “p”, and “q” functions can all be used from `nimbleFunctions` (and in BUGS model code), but the care is needed in the syntax.

- We support only the canonical NIMBLE parameterization, as listed below (with a small number of exceptions, also listed).
- The names of the distributions are the names used under the hood in NIMBLE and differ from the standard BUGS distribution names.
- Currently “r” functions only return one random draw at a time, and the first argument must always be 1.
- For the multivariate normal and Wishart distributions the `prec_param` or `scale_param` argument must be provided, indicating when a covariance or precision matrix has been given.

User-defined distributions can also be used from `nimbleFunctions`. Arguments are matched by order or by name (if given). If omitted, default argument values based on the standard R distribution functions will be used. Standard arguments to distribution functions in R (`log`, `log.p`, `lower.tail`) can be used and take the usual default values as in R. User-supplied distributions are handled analogously with regard to matching by position and use of defaults (when provided via the `nimbleFunction` run-time arguments) (Section 5.2.5).

Supported distributions include:

- `dbinom(size, prob)`
- `dcat(prob)`
- `dmulti(size, prob)`
- `dnbinom(size, prob)`
- `dpois(lambda)`

- `dbeta(shape1, shape2)`
- `dchisq(df)`
- `dexp(rate)`
- `dexp_nimble(rate)`
- `dexp_nimble(scale)`
- `dgamma(shape, rate)`
- `dgamma(shape, scale)`
- `dlnorm(meanlog, sdlog)`
- `dlogis(location, scale)`
- `dnorm(mean, sd)`
- `dt_nonstandard(df, mu, sigma)`
- `dt(df)`
- `dunif(min, max)`
- `dweibull(shape, scale)`
- `ddirch(alpha)`
- `dmnorm_chol(mean, cholesky, prec_param)`
- `dwish_chol(cholesky, df, scale_param)`

In the last two, `cholesky` stands for Cholesky decomposition of the relevant matrix; `prec_param` indicates whether the Cholesky is of a precision matrix or covariance matrix; and `scale_param` indicates whether the Cholesky is of a scale matrix or an inverse scale matrix.

In a future release, we will also extend the alternative parameterizations given in Section 5.2.2 to `nimbleFunctions`.

9.6 Some options for reducing memory usage

NIMBLE can make a lot of objects in its processing, and some of them use R features like reference classes that are not light in memory usage. We have noticed that building large models can use lots of memory. To help alleviate this, we provide two options, which can be controlled via `nimbleOptions`. As noted above, the option `useMultiInterfaceForNestedNimbleFunctions` defaults to `TRUE`, which means NIMBLE will not build full interfaces to compiled `nimbleFunctions` that only appear within other `nimbleFunctions`. If you want access to all such `nimbleFunctions` use `useMultiInterfaceForNestedNimbleFunctions = FALSE`. The option `clearNimbleFunctionsAfterCompiling` is more drastic, and it is experimental, so “buyer beware”. This will clear much of the contents of an uncompiled `nimbleFunction` object after it has been compiled in an effort to free some memory. We expect to be able to keep making NIMBLE more efficient – faster execution and lower memory use – in the future.
